(Editors)
Richard Kelsey, William Clinger, Jonathan Rees
(Editors, Revised⁵ Report on the Algorithmic Language Scheme)
Robert Bruce Findler, Jacob Matthews
(Authors, formal semantics)

26 September 2007

SUMMARY

The report gives a defining description of the programming language Scheme. Scheme is a statically scoped and properly tail-recursive dialect of the Lisp programming language invented by Guy Lewis Steele Jr. and Gerald Jay Sussman. It was designed to have an exceptionally clear and simple semantics and few different ways to form expressions. A wide variety of programming paradigms, including functional, imperative, and message passing styles, find convenient expression in Scheme.

This report is accompanied by a report describing standard libraries [?]; references to this document are identified by designations such as "library section" or "library chapter". It is also accompanied by a report containing non-normative appendices [?]. A fourth report gives some historical background and rationales for many aspects of the language and its libraries [?].

The individuals listed above are not the sole authors of the text of the report. Over the years, the following individuals were involved in discussions contributing to the design of the Scheme language, and were listed as authors of prior reports:

Hal Abelson, Norman Adams, David Bartley, Gary Brooks, William Clinger, R. Kent Dybvig, Daniel Friedman, Robert Halstead, Chris Hanson, Christopher Haynes, Eugene Kohlbecker, Don Oxley, Kent Pitman, Jonathan Rees, Guillermo Rozas, Guy L. Steele Jr., Gerald Jay Sussman, and Mitchell Wand.

In order to highlight recent contributions, they are not listed as authors of this version of the report. However, their contribution and service is gratefully acknowledged.

We intend this report to belong to the entire Scheme community, and so we grant permission to copy it in whole or in part without fee. In particular, we encourage implementors of Scheme to use this report as a starting point for manuals and other documentation, modifying it as necessary.

INTRODUCTION

Языки программирования должны разрабатываться не путём накопления функциональных возможностей, а путём удаления слабостей и ограничений, приводящих к кажущейся необходимости дополнительных средств. Scheme демонстрирует, что очень небольшого количества правил для построения выражений без ограничений на их составления достаточно для формирования практического и эффективного языка программирования, который является достаточно гибким, чтобы поддержать большинство основных парадигм программирования, используемых в настоящее время.

Scheme был одним из первых языков программирования, который включает полноценные процедуры, как в лямбдаисчислении, таким образом доказывая полноценность статических правил области видимости и блочной структуры в языке с динамической типизацией. Scheme был первым основным диалектом, Lisp, чтобы отличить процедуры от лямбда-выражений и символов, чтобы использовать единственное лексическое окружение для всех переменных, и чтобы вычислить позицию оператора вызова процедуры таким же образом как позицию операнда. Полагаясь полностью на запросы процедуры выражать повторение, Scheme подчеркнул факт, что рекурсивные хвостом запросы процедуры являются по существу gotos теми аргументами прохода. Scheme был первым широко используемым языком программирования, который охватит первоклассные процедуры спасения, из которых могут синтезироваться все предварительно известные последовательные структуры контроляуправления. Последующая версия Scheme вводила понятиеконцепцию точных и неточных объектов числаномера, расширение родовой арифметики ОбщегоОбычного Лиспа. Позже, Scheme стал первым языком программирования, который поддержит гигиеническое макроопределениемакрос, которые разрешают синтаксису языка с блочной структурой быть расширенным в последовательной и надежной манере.

Руководящие принципы

Чтобы помогать вести усилие по стандартизации, редакторы приняли ряд принципов, представленных ниже. Как язык Scheme, определенный в *Revised*⁵ *Report on the Algorithmic Language Scheme* [?] язык, описанный в этом сообщении предназначен:

- позвольте программистам читать код друг друга, и позволять разработку портативных программ, которые могут быть выполнены в любой соответствующей реализации Scheme:
- derive its power from simplicity, a small number of generally useful core syntactic forms and procedures, and no unnecessary restrictions on how they are composed;
- allow programs to define new procedures and new hygienic syntactic forms;
- support the representation of program source code as data;

- make procedure calls powerful enough to express any form of sequential control, and allow programs to perform nonlocal control operations without the use of global program transformations;
- allow interesting, purely functional programs to run indefinitely without terminating or running out of memory on finite-memory machines;
- allow educators to use the language to teach programming effectively, at various levels and with a variety of pedagogical approaches; and
- allow researchers to use the language to explore the design, implementation, and semantics of programming languages.

In addition, this report is intended to:

- allow programmers to create and distribute substantial programs and libraries, e.g., implementations of Scheme Requests for Implementation, that run without modification in a variety of Scheme implementations;
- support procedural, syntactic, and data abstraction more fully by allowing programs to define hygiene-bending and hygiene-breaking syntactic abstractions and new unique datatypes along with procedures and hygienic macros in any scope;
- allow programmers to rely on a level of automatic run-time type and bounds checking sufficient to ensure type safety; and
- allow implementations to generate efficient code, without requiring programmers to use implementation-specific operators or declarations.

While it was possible to write portable programs in Scheme as described in *Revised*⁵ *Report on the Algorithmic Language Scheme*, and indeed portable Scheme programs were written prior to this report, many Scheme programs were not, primarily because of the lack of substantial standardized libraries and the proliferation of implementation-specific language additions.

In general, Scheme should include building blocks that allow a wide variety of libraries to be written, include commonly used user-level features to enhance portability and readability of library and application code, and exclude features that are less commonly used and easily implemented in separate libraries.

The language described in this report is intended to also be backward compatible with programs written in Scheme as described in *Revised*⁵ *Report on the Algorithmic Language Scheme* to the extent possible without compromising the above principles and future viability of the language. With respect to future viability, the editors have operated under the assumption that many more Scheme programs will be written in the future than exist in the present, so the future programs are those with which we should be most concerned.

Acknowledgements

Many people contributed significant help to this revision of the report. Specifically, we thank Aziz Ghuloum and André van Tonder for contributing reference implementations of the library system. We thank Alan Bawden, John Cowan, Sebastian Egner, Aubrey Jaffer, Shiro Kawai, Bradley Lucier, and André van Tonder for contributing insights on language design. Marc Feeley, Martin Gasbichler, Aubrey Jaffer, Lars T Hansen, Richard Kelsey, Olin Shivers, and André van Tonder wrote SRFIs that served as direct input to the report. Marcus Crestani, David Frese, Aziz Ghuloum, Arthur A. Gleckler, Eric Knauel, Jonathan Rees, and André van Tonder thoroughly proofread early versions of the report.

We would also like to thank the following people for their help in creating this report: Lauri Alanko, Eli Barzilay, Alan Bawden, Brian C. Barnes, Per Bothner, Trent Buck, Thomas Bushnell, Taylor Campbell, Ludovic Courtès, Pascal Costanza, John Cowan, Ray Dillinger, Jed Davis, J.A. "Biep" Durieux, Carl Eastlund, Sebastian Egner, Tom Emerson, Marc Feeley, Matthias Felleisen, Andy Freeman, Ken Friedenbach, Martin Gasbichler, Arthur A. Gleckler, Aziz Ghuloum, Dave Gurnell, Lars T Hansen, Ben Harris, Sven Hartrumpf, Dave Herman, Nils M. Holm, Stanislav Ievley, James Jackson, Aubrey Jaffer, Shiro Kawai, Alexander Kjeldaas, Eric Knauel, Michael Lenaghan, Felix Klock, Donovan Kolbly, Marcin Kowalczyk, Thomas Lord, Bradley Lucier, Paulo J. Matos, Dan Muresan, Ryan Newton, Jason Orendorff, Erich Rast, Jeff Read, Jonathan Rees, Jorgen Schäfer, Paul Schlie, Manuel Serrano, Olin Shivers, Jonathan Shapiro, Jens Axel Søgaard, Jay Sulzberger, Pinku Surana, Mikael Tillenius, Sam Tobin-Hochstadt, David Van Horn, André van Tonder, Reinder Verlinde, Alan Watson, Andrew Wilcox, Jon Wilson, Lynn Winebarger, Keith Wright, and Chongkai Zhu.

We would like to thank the following people for their help in creating the previous revisions of this report: Alan Bawden. Michael Blair, George Carrette, Andy Cromarty, Pavel Curtis, Jeff Dalton, Olivier Danvy, Ken Dickey, Bruce Duba, Marc Feeley, Andy Freeman, Richard Gabriel, Yekta Gürsel, Ken Haase, Robert Hieb, Paul Hudak, Morry Katz, Chris Lindblad, Mark Meyer, Jim Miller, Jim Philbin, John Ramsdell, Mike Shaff, Jonathan Shapiro, Julie Sussman, Perry Wagle, Daniel Weise, Henry Wu, and Ozan Yigit.

We thank Carol Fessenden, Daniel Friedman, and Christopher Haynes for permission to use text from the Scheme 311 version 4 reference manual. We thank Texas Instruments, Inc. for permission to use text from the TI Scheme Language Reference Manual [?]. We gladly acknowledge the influence of manuals for MIT Scheme [?], T [?], Scheme 84 [?], Common Lisp [?], Chez Scheme [?], PLT Scheme [?], and Algol 60 [?].

We also thank Betty Dexter for the extreme effort she put into setting this report in T_FX, and Donald Knuth for designing the program that caused her troubles.

The Artificial Intelligence Laboratory of the Massachusetts Institute of Technology, the Computer Science Department of Indiana University, the Computer and Information Sciences

Department of the University of Oregon, and the NEC Research Institute supported the preparation of this report. Support for the MIT work was provided in part by the Advanced Research Projects Agency of the Department of Defense under Office of Naval Research contract N00014-80-C-0505. Support for the Indiana University work was provided by NSF grants NCS 83-04567 and NCS 83-03325.

ОПИСАНИЕ ЯЗЫКА

1. Введение в Scheme

В данной главе описано введение в семантику Scheme. Целью данного введения является объяснение фундаментальных концепций языка, достаточных для облегчения понимания последующих глав работы, организованных в виде справочного руководства. Поэтому данный краткий обзор не является полным введением в язык, и при этом он не всегда точен в некоторых аспектах или не всегда нормативен.

После Algol Scheme является языком программирования со статическими областями видимости. Каждое использование переменной ассоциировано с лексически явным связыванием этой переменной.

Scheme имеет неявные, в отличие от декларативных, типы[?]. Типы связаны с объектами (также называемыми значениями), а не с переменными. (Некоторые авторы называют языки с неявными типами нетипизированными, слабо типизированными или динамически типизированными языками.) Другими языками с неявными типами являются Python, Ruby, Smalltalk, а также другие диалекты Lisp. Языки с декларативными типами (иногда называемые строго типизированными или статически типизированными языками) включают Algol 60, C, C#, Java, Haskell и ML.

Все объекты, созданные в процессе вычисления Scheme, включая процедуры и продолжения, имеют неограниченный экстент. Ни один объект Scheme никогда не разрушается. Причина того, что реализации Scheme полностью не расходуют (обычно!) память, состоит в том, что им разрешается возвращать память, занятую объектом, если они смогут выяснить, что объект не имеет возможности влиять ни на одно будущее вычисление. Другие языки, в которых большинство объектов имеет неограниченный экстент, включают С#, Java, Haskell, большинство диалектов Lisp, ML, Python, Ruby и Smalltalk.

Реализации Scheme должны подчиняться правилам хвостовой рекурсии. Это даёт возможность выполнения итеративного вычисления в постоянном пространстве, даже если итеративное вычисление описано синтаксически рекурсивной процедурой. Таким образом, при реализации поддержки хвостовой рекурсии, итерация может быть выражена с помощью обычной техники вызова процедуры, так, чтобы специальные итеративные конструкции были применимы только в качестве синтаксического сахара.

Scheme был одним из первых языков, поддерживающих процедуры как объекты сами по себе. Процедуры могут динамически создаваться, сохраняться в структурах данных, возвращаться как результаты процедур, и так далее. Другие языки с этими свойствами включают Common Lisp, Haskell, ML, Ruby и Smalltalk.

Одной из отличительных особенностей Scheme является то, что продолжения, которые в большинстве других языков функционируют только внутренне, также имеют "первоклассный" статус. Первоклассные продолжения полезны для реализации широкого разнообразия передовых управля-

ющих конструкций, включая нелокальные выходы, бектрекинг и сопрограммы.

Выражения аргументов вызова процедуры в Scheme вычисляются перед получением процедурой управления независимо от необходимости для процедуры результата вычисления. С, С#, Common Lisp, Python, Ruby и Smalltalk - другие языки, которые всегда вычисляют выражения аргументов перед вызовом процедуры. Это отличается от семантики ленивого вычисления Haskell или семантики вызова по имени Algol 60, где выражение аргумента не вычисляется, если процедура не нуждается в его значении.

Арифметическая модель Scheme предоставляет богатый набор численных типов и операций с ними. Кроме того, она различает *точные* и *неточные* числовые объекты: По существу, точный числовой объект точно соответствует числу, а неточный числовой объект является результатом вычисления, которое повлекло за собой округление или другие ошибки.

1.1. Основные типы

Программы Scheme оперируют *объектами*, которые также называются *значениями*. Объекты Scheme организованы в наборы значений, которые называются *типами*. В этой секции дан краткий обзор существенно важных типов языка Scheme. Больше типов описано в последующих главах.

Note: Поскольку Scheme латентно типизирован, использование термина *тип* в данной работе отличается от использования термина в контексте других языков, особенно с явно объявляемой типизацией.

Булевые Булевый тип является истинностным значением и может быть true или false. Объект "false" в Scheme записывается #f. Объект "true" записывается #t. В большинстве мест, где ожидается истинностное значение, однако, любой объект, отличный от #f интерпретитуется как true.

Числовые Scheme поддерживает множество числовых типов данных, включая объекты, представляющие целые числа произвольной точности, рациональные числа, сложные числа и приближённые числа различных видов. В Главе 3 дан краткий обзор структуры башни численных типов Scheme.

Знаковые Символы Scheme по большей части соответствуют текстовым символам. Более точно, они изоморфны к скалярным величинам стандарта Unicode.

Строковые Строки являются конечными последовательностями символов фиксированной длины и, таким образом, представляют произвольные тексты Unicode.

Символьные Символ является объектом, представляющим строку, имя символа. В отличие от строки, два символа, имена которых записаны в том же порядке, никоим образом не различаются. Символы полезны для многих применений; например, они могут использоваться, перечислимые значения пути используются на других языках.

Пары и списки Пара является структурой данных с двумя компонентами. Наиболее общее применение пар относится к представлению (отдельно связанных) списков, где первый компонент ("car") представляет первый элемент списка, а второй компонент ("cdr") - остальную часть списка. Scheme также имеет отдельный пустой список, который является последним cdr в цепочке пар, формирующих список.

Векторы Векторы, как и списки, являются линейными структурами данных, представляющими конечные последовательности произвольных объектов. Поскольку к элементам списка получают доступ последовательно через цепь пар, представляющих его, к элементам вектора обращаются целыми индексами. Таким образом, векторы предпочтительнее списков для произвольного доступа к элементам.

Процедуры В Scheme процедуры являются значениями.

1.2. Выражения

Важнейшими элементами кода Scheme являются выражения. Выражения могут быть вычислены, порождая значение. (Фактически, любое количество значений—см. раздел 5.8.) Самые фундаментальные выражения - литеральные выражения:

#t
$$\Longrightarrow$$
 #t \Longrightarrow 23

Эта форма записи означает, что выражение #t вычисляется как #t, то есть, значение для "true", и что выражение 23 вычисляется к численному объекту, представляющему число 23.

Составные выражения формируются помещением круглых скобок вокруг своих подвыражений. Первое подвыражение идентифицирует операцию; остальные подвыражения являются операндами операции:

$$(+ 23 42) \Rightarrow 65$$

$$(+ 14 (* 23 42)) \Rightarrow 980$$

В начале этого примера + является именем встроенной операции сложения, а 23 и 42 - операндами. Выражение (+ 23 42) читается как "сумма 23 и 42". Составные выражения могут вкладываться—следующий пример читается как "сумма 14 и произведения 23 и 42".

Как показывают эти примеры, составные выражения в Scheme всегда записываются с помощью одной и той же префиксной нотации. Следствием является необходимость круглых скобок для указания структуры. Следовательно, "лишние" круглые скобки, которые часто допускаются в математической нотации, а также во многих языках программирования, в Scheme не позволяются.

Как и во многих других языках, пробельные символы (включая конец строки) являются не значащими, когда они отделяют подвыражения выражений, и могут использоваться для указания структуры.

1.3. Переменные и компоновка

Scheme позволяет привязывать идентификаторы к содержащим значения ячейкам памяти. Такие идентификаторы называются переменными. Во многих случаях, определенно когда значение ячейки памяти никогда не изменяется после её создания, полезно думать о переменной как привязанной к значению непосредственно.

(let ((x 23)
 (y 42))
 (+ x y))
$$\implies$$
 65

В данном случае выражение, начинающееся с let - конструкция привязки. Заключённая в скобки структура после **let** перечисляет переменные совместно с выражениями: переменная ж совместно с 23 и переменная у совместно с 42. Выражение let связывает x с 23 и y с 42. Эти привязки доступны в mеле выражения let, (+ x y), и только там.

1.4. Определения

Переменные, связанные выражением let, являются локальными, так как их связывания видимы только в теле **let**. Scheme также позволяет создавать связывания верхнего уровня для идентификаторов следующим образом:

(Они фактически являются "верхним уровнем" в теле программы верхнего уровня или библиотеки; см. секцию 1.12 ниже.)

Первые две заключенные в скобки структуры являются определениями; они создают связывания верхнего уровня, связывая x с 23, а у с 42. Определения не являются выражениями и не могут находиться там, тде где может находиться выражение. Кроме того, определение не имеет значения.

Связывания функционируют в соответствии с лексической структурой программы: При наличии нескольких связываний с одним именем переменная соотносится с ближайшим к нему связыванием, начиная от её появления в программе и продвижения изнутри вовне, и со связыванием верхнего уровня, если локальное связывание не может быть найдено по пути:

```
(define x 23)
(define y 42)
(let ((y 43))
```

$$(+ x y)) \implies 66$$

$$(let ((y 43))$$

$$(let ((y 44))$$

$$(+ x y))) \implies 67$$

1.5. Формы

Хотя определения не являются выражениями, составные выражения и определения имеют схожую синтаксическую структуру:

При этом первая линия содержит определение, а следующая - выражение, данное различие основывается на связывании define и *. На чисто синтаксическом уровне обе являются формами, а форма является обобщённым названием синтаксической части программы Scheme. В частности, 23 является подформой формы (define x 23).

1.6. Процедуры

Определения могут также использоваться для определения процедур.

Процедура, несколько упрощённо, является абстракцией выражения посредством объектов. В первом определении примера определена процедура, названная **f**. (Обратите внимание на круглые скобки вокруг **f x**, обозначающие, что это - определение процедуры.) Выражение (**f** 23) является вызовом процедуры, приблизительно означающим "вычислить (**+ x** 42) (тело процедуры) с **x**, привязанным к 23".

Поскольку процедуры являются объектами, их можно передавать в другие процедуры:

В этом примере тело g вычисляется c p, привязанным k f, u x, привязанным k 23, что эквивалентно (f 23) и вычисляется как 65.

Фактически многие предопределённые операции Scheme обеспечиваются не синтаксисом, а переменными, значениями которых являются процедуры. Операция +, например, приобретающая специальную синтаксическую трактовку во многих других языках, в Scheme является всего лишь регулярным идентификатором, связанным с процедурой, складывающей числовые объекты. То же самое касается и *, и многих других:

```
(define (h op x y)
(op x y))
(h + 23 42) ⇒ 65
(h * 23 42) ⇒ 966
```

Определения процедур - не единственный способ создания процедур. **lambda**-выражение создаёт новую процедуру в качестве объекта без необходимости указания имени:

$$((lambda(x) (+ x 42))23) \implies 65$$

Всё выражение в этом примере является вызовом процедуры; (lambda (x) (+ x 42)) вычисляется как процедура, принимающая одиночный числовой объект и добавляющая к нему 42.

1.7. Вызовы процедур и синтаксические ключевые слова

Хотя и (+ 23 42), и (f 23), и ((lambda (x) (+ x 42)) 23) являются примерами вызовов процедур, выражения lambda и let - нет. Это потому что let, хоть и идентификатор, но не переменная, а синтаксическое ключевое слово. Форма, содежащая синтаксическое ключевое слово в качестве своего первого подвыражения, подчиняется специальным правилам, определяемым ключевым словом. Идентификатор define в определении также является синтаксическим ключевым словом. Следовательно, определения также не являются вызовами процедур.

Правилами для ключевого слова **lambda** определено, что первая подформа является списком параметров, а остальные подформы - телом процедуры. В выражении **let** первая подформа является списком спецификаций привязки, а остальные подформы образовывают тело выражений.

Обычно вызовы процедур можно отличить от таких специальных форм, с помощью поиска синтаксического ключевого слова в первом положении формы: если в первое положении не содержится синтаксического ключевого слова, выражение является вызовом процедуры. (Так называемый макрос идентификатора позволяет создавать другие виды специальных форм, но сравнительно редко.) Набор синтаксических ключевых слов Scheme является довольно небольшим, что обычно делает эту задачу довольно простой. Возможно, однако, создание новых привязок для синтаксических ключевых слов; см. секцию 1.9 ниже.

1.8. Присваивание

Переменные Scheme, связанные с определениями или с выражениями **let** или **lambda**, привязываются фактически не непосредственно к объектам, определённым в соответствующих привязках, а к адресам памяти, содержащим эти объекты. Содержимое по этим адресам впоследствии может быть деструктивно изменено с помощью присваивания:

В данном случае тело выражения **let** состоит из двух вычисляемых последовательно выражений со значением финального выражения, принимающего значение всего выражения let. Выражение (set! x 42), является присваиванием, указывающим "заменить объект по адресу, на который указывает ж, на 42". Таким образом, предыдущее значение ж - 23 изменяется на 42.

1.9. Производные формы и макросы

Большинство специальных форм, определённых в данной работе, могут быть приведены к более простым специальным формам. Например, выражение let может быть приведено к вызову процедуры и выражению lambda. Следующие два выражения эквивалентны:

```
(let ((x 23)
     (y 42))
 (+ x y))
                        ⇒ 65
((lambda (x y) (+ x y)) 23 42)
        ⇒ 65
```

Специальные формы, такие, как выражения let, называются производными формами, так как их семантика может быть получена из того или иного вида форм синтаксическим преобразованием. Некоторые определения процедур также являются производными формами. Следующие два определения эквивалентны:

```
(define (f x)
  (+ \times 42))
(define f
  (lambda (x)
    (+ \times 42)))
```

В программе Scheme имеется возможность создания своих собственных производных форм путём связывания синтаксических ключевых слов с макросами:

```
(define-syntax def
  (syntax-rules ()
    ((def f (p ...) body)
    (define (f p ...)
      body))))
(def f (x)
 (+ \times 42))
```

Конструкция define-syntax определяет, что заключенная в скобки структура, соответствующая шаблону (def f (р ...) body), где **f**, **p** и body - переменные шаблона, приводится к (define (f p ...) body). Таким образом, форма def, находящаяся в примере, приводится к:

```
(define (f x)
  (+ \times 42))
```

Возможность создания новых синтаксических ключевых слов делает Scheme чрезвычайно гибким и выразительным, что позволяет большинству особенностей, встроенных в другие языки, быть производными формами в Scheme.

1.10. Синтаксические данные и базисные значения

Подмножество объектов Scheme называется базисными значениями. Они включают булевы, численные объекты, знаки, символы и строки, равно как и списки и векторы, элементы которых являются данными. Каждое базисное значение может быть представлено в текстовом виде как синтаксический базис, который может быть записан и прочитан без потери информации. Базисное значение может быть представлено несколькими разными синтаксическими данными. Кроме того, каждое базисное значение может быть тривиально приведено к литеральному выражению в программе путём добавления ' к соответствующему синтаксическому базису:

```
<sup>'</sup> 23
                                      ⇒ 23
/#t

    #t
foo'
                                      \Longrightarrow foo
                                      \implies (1 2 3)
' (1 2 3)
/#(1 2 3)
                                      \implies #(1 2 3)
```

', показанный в предыдущих примерах, не нужен для представлений численных объектов или булевых переменных. Синтаксический базис **foo** представляет символ с именем "foo", а 'foo - литеральное выражение с этим символом в качестве его значения. (1 2 3) - синтаксический базис, представляющий список с элементами 1, 2 и 3, а ' (1 2 3) - литеральное выражение с этим списком в качестве его значения. Аналогично, #(1 2 3) - синтаксический базис, представляющий вектор с элементами 1, 2 и 3, а '#(1 2 3) - соответствующий литерал.

Синтаксические данные являются расширенным набором форм Scheme. Таким образом, данные могут использоваться, для представления форм Scheme в виде объектов данных. В частности, символы могут использоваться для представления идентификаторов.

```
' (+ 23 42)

⇒ (+ 23 42)
'(define (f x) (+ x 42))
         \implies (define (f x) (+ x 42))
```

Это облегчает написание программ, работающих с исходным кодом Scheme, в частности, интерпретаторов и программных преобразователей.

1.11. Продолжения

Всякий раз, когда выражение Scheme оценено есть продолжение, ожидая результат выражения. Продолжение представляет все будущее (по умолчанию) для вычисления. Например, произвольно, продолжение 3 в выражении

добавляет 1 к нему. Обычно эти встречающиеся повсюду продолжения скрыты на заднем плане, и программисты особо не заботятся о них. В редких случаях, однако, программист, возможно, должен иметь дело с продолжениями явно. Процедура call-with-current-continuation

(см. секцию 11.15) позволяет программистам Scheme делать это, создавая процедуру, которая восстанавливает текущее продолжение. Процедура call-with-currentcontinuation принимает процедуру, вызывает её немедленно с аргументом, который является аварийной процедурой. Эту аварийную процедуру можно тогда вызвать с аргументом, который становится результатом вызова callwith-current-continuation. Таким образом, аварийная процедура оставляет ее собственное продолжение, и восстанавливает продолжение вызова к call-withcurrent-continuation.

В следующем примере, аварийная процедура, представляющая продолжение, которое добавляет 1 к его аргументу, привязана к ессаре, и затем вызывается с 3 как аргумент. Продолжение вызова escape оставлено, и вместо этого эти 3 передают к продолжению, которое добавляет 1:

```
(+ 1 (call-with-current-continuation
      (lambda (escape)
       (+ 2 (escape 3)))))
```

Аварийная процедура имеет неограниченный экстент: Она может быть вызвана после вызова захватившего его продолжения, и это можно вызвать несколько раз. Это делает call-with-current-continuation значительно более мощным чем типичные нелокальные управляющие конструкции, типа исключений в других языках.

1.12. Библиотеки

Код Scheme может быть организован в компонентах, которые называются библиотеками. Каждая библиотека содержит определения и выражения. Она может импортировать определения из других библиотек и экспортировать определения в другие библиотеки.

Следующая библиотека называется (hello), экспортирует определение, которое называется hello-world, и импортирует основную библиотеку (см. главу 11), и простая библиотека І/О (см. библиотечную секцию ??). Экспорт hello-world является процедурой, которая показывает Hello World на отдельной линии:

```
(library (hello)
 (export hello-world)
 (import (rnrs base)
        (rnrs io simple))
 (define (hello-world)
   (display "Hello World")
   (newline)))
```

1.13. Программы верхнего уровня

Программа Scheme активизируется посредством программы верхнего уровня. Как и библиотека, программа верхнего уровня содержит импорт, определения и выражения, и определяет точку входа для выполнения. Таким образом, программа верхнего уровня определяет, через замкнутое выражение библиотек, которые это импортирует, программу Scheme.

Следующая программа верхнего уровня получает первый аргумент из командной строки через процедуру commandline из библиотеки (rnrs programs (6)) (см. библиотечную главу ??). Это тогда открывает файл с помощью open-file-input-port (см. секцию ??, приводя к порт, т.е. к связи с файлом как источником данных, и вызывает процедуру get-bytes-all получения содержимого файла в виде двоичных данных. Это тогда использует putbytes для вывода содержимого файла в стандартный вывод:

```
#!r6rs
(import (rnrs base)
       (rnrs io ports)
       (rnrs programs))
(put-bytes (standard-output-port)
         (call-with-port
             (open-file-input-port
               (cadr (command-line)))
           get-bytes-all))
```

Уровни требований 2.

Ключевые слова, "must", "must not" "should", "should not", "recommended", "may", и "optional" в данной работе должны интерпретироваться как описано в RFC 2119 [?]. А именно:

must Это слово означает, что инструкция является абсолютным требованием спецификации.

must not Эта фраза означает, что инструкция является абсолютным запрещением спецификации.

should Это слово, или прилагательное "recommended", означают, что в особых обстоятельствах могут существовать веские причины для игнорирования инструкции, но перед выбором иной линии поведения последствия должны быть осознаны и взвешены.

should not Эта фраза, или фраза "not recommended", означают, что в особых обстоятельствах могут существовать веские причины для принятия функционирования инструкции, но перед выбором описываемой инструкцией линии поведения последствия должны быть осознаны и взвешены.

may Это слово, или прилагательное "optional" означают, что элемент является действительно дополнительным.

В частности, "should" в данной работе иногда используется для обозначения обстоятельств, лежащих вне спецификации данной работы, но не обнаруживаемых реализацией на практике; см. секцию 5.4. При таких обстоятельствах конкретная реализация может позволить программисту игнорировать рекомендацию в данной работе и даже демонстрировать адекватное функционирование. Однако, поскольку данная работа не специфицирует функционирование, такие программы могут быть непортируемыми, то есть, их выполнение может привести к различным результатам в разных реализациях.

Кроме того, в данной работе иногда используется фраза "not required" для обозначения отсутствия абсолютного требования.

3. Числа

В этой главе описывается модель Scheme для чисел. Важно различать математические числа, объекты Scheme, стремящиеся представить их, машинные представления, используемые для реализации чисел, и используемые для записи чисел нотации. В данной работе термин число относится к математическому числу, а термин числовой объект - к объекту Scheme, представляющему число. В данной работе используются типы complex, real, rational и integer для обращения и к математическим числам, и к числовым объектам. Типы fixnum и flonum относятся к специальным подмножествам числовых объектов, как определяется общими машинными представлениями и объясняется ниже.

3.1. Числовая башня

Числа могут быть квалифицированы башней подмножеств, в которой каждый уровень является подмножеством уровня выше него:

number complex real rational integer

Например, 5 является целым числом. Поэтому 5 также является рациональным, действительным и комплексным. То же верно и для числовых объектов, представляющих 5.

Числовые объекты организованы как соответствующая башня подтипов, определённых предикатами **number?**, **complex?**, **real?**, **racional?**, и **integer?**; см. секцию 11.7.4. Числовые объекты целого также называются объектами целого.

Не существует очевидной взаимосвязи между подмножеством, содержащим число, и его представлением в компьютере. Например, целое число 5 может иметь несколько представлений. Операции с числами в Scheme интерпретируют числовые объекты как абстрактные данные, столь же независимые от их представления, насколько возможно. Хотя реализация Scheme может использовать множество различных представлений чисел, это не должно быть очевидно случайному программисту, пишущему простые программы.

3.2. Точность

Целесообразно различать числовые объекты, о которых известно, что они точно соответствуют числу, и числовые объекты, вычисление которых повлекло за собой округление или другие ошибки. Например, операциям индексации

структур данных может потребоваться знание точного индекса, как и некоторым операциям с коэффициентами полинома в системе символьной алгебры. С другой стороны, результаты измерений являются неточными по определению, и иррациональные числа могут быть апроксимированы рациональной, и поэтому неточной, апроксимацией. Для обнаружения использования чисел, известных только приблизительно, там, где требуются точные числа, Scheme явно различает точные числовые объекты от неточных. Это различие независимо от измерения типа.

Числовой объект является точным, если он является значением точного числового литерала или был получен из точных числовых объектов с помощью только точных операций. Точные числовые объекты соответствуют математическим числам явным образом.

В свою очередь, числовой объект является неточным, если он является значением неточного числового литерала или был получен из неточных числовых объектов числа, или с помощью неточных операций. Таким образом неточность передаётся непосредственно.

Точная арифметика безопасна в следующем смысле: Если точные числовые объекты передаются любой из арифметических процедур, описанных в секции 11.7.1, и возвращается точный числовой объект, результат математически корректен. Это в общем случае не верно для вычислений с использованием неточных числовых объектов, так как могут использоваться методы аппроксимации, типа арифметики с плавающей запятой, но это уже является обязанностью каждой реализации - выдать результат как можно ближе практически к математически идеальному результату.

3.3. Fixnums and flonums

fixnum является точным объектом целого, который лежит в пределах конкретного зависимого от реализации поддиапазона точного объекта целого. (В секции ?? описана библиотека для вычислений с fixnums.) Аналогично, каждая реализация должно обозначать подмножество своих неточных вещественных числовых объектов как *flonums*, и преобразовывать конкретные внешние представления в flonums. (В секции ?? описана библиотека для вычислений с flonums.) Заметьте, что не подразумевается, что реализация должна использовать представления с плавающей запятой.

3.4. Требования к реализациям

Реализации Scheme должны поддерживать числовые объекты для всей башни подтипов, приведённых в секции 3.1. Кроме того, реализации должны поддерживать точные объекты целого точные рациональные числовые объекты практически неограниченного размера и точности, и реализовывать конкретные процедуры (перечисленные в 11.7.1) с тем, чтобы они всегда возвращали точные результаты при предоставлении точных аргументов. ("Практически неограничен-

12 Revised⁶ Scheme

ный" означает, что размер и точность таких чисел должны ограничиваться только размером доступной памяти.)

Реализации могут поддерживать только ограниченный диапазон неточных числовых объектов любого типа, подчининяясь требованиям данной секции. Например, реализация может ограничить диапазон неточных вещественных числовых объектов (и, следовательно, диапазон неточных целых и рациональных числовых объектов) динамическим диапазоном формата flonum. Кроме того, зазоры между неточными целыми объектами и rationals, вероятно, будут очень большими в такой реализации при приближении к границам этого диапазона.

Реализация может использовать плавающую запятую и другие неточные способы представления неточных чисел. В данной работе рекомендуется, но не требуется, чтобы реализации, использующие представления с плавающей запятой, следовали стандартам плавающей запятой IEEE, а реализации, использующие другие представления, должны иметь точность, соответствовующую или превышающую точность, достигаемую этими стандартами с плавающей запятой [?].

В частности, реализации, использующие представления с плавающей запятой, должны соблюдать следующие правила: результат с плавающей запятой должен быть представлен с точностью, по крайней мере не менее используемой для выражения любого неточного аргумента в данной операции. При применении потенциально неточных операций, типа sqrt к точным аргументам должны выдаваться точные ответы всегда, когда возможно (например, квадратный корень точного 4 должен быть точным 2). Однако это не является требованием. Если, с другой стороны, точным числовым объектом управляют с целью получения неточного результата (как sqrt), и если результат представляется с плавающей запятой, должен использоваться самый точный доступный формат с плавающей запятой; но если результат представлен неким иным способом, тогда, представление должно иметь точность, по крайней мере не менее самого точного доступного формата с плавающей запятой.

Недопущение использования неточных числовых объектов со слишком большим для представления в реализации значением или значащей частью является заботой программистов.

3.5. Бесконечность и NaN

Некоторое реализации Scheme, например, придерживающиеся стандартов IEEE с плавающей точкой, различают специальные числовые объекты, называемые положительная бесконечность, отрицательная бесконечность и NaN.

Положительная бесконечность рассматривается как неточный вещественный (но не рациональный) числовой объект, представляющий неопределённое число, большее, чем числа, представляемые всеми рациональными числовыми объектами. Отрицательная бесконечность рассматривается как неточный вещественный (но не рациональный) числовой объект, представляющий неизвестное число, меньшее, чем числа, представляемые всеми рациональными числами.

NaN рассматривается как неточный вещественный (но не рациональный) числовой объект, настолько неопределён-

ный, что он может представлять любое вещественное число, включая положительную или отрицательную бесконечность, и даже может быть больше положительной бесконечности или меньше отрицательной бесконечности.

3.6. Распознавание -0.0

Некоторые реализации Scheme, например, придерживающиеся стандартов IEEE с плавающей точкой, различают числовые объекты 0.0 и -0.0, то есть, положительный и отрицательный неточный ноль. В данной работе в ряде случаев специфицируется функционирование конкретных арифметических операций с такими числовыми объектами. Такие спецификации записываются вместе с "если -0.0 распознан" или "реализация, различающая -0.0".

4. Лексический и datum-синтаксис

Синтаксис кода Scheme организован на трёх уровнях:

- 1. *Лексический синтаксис*, описывающий, как текст программы разбивается на последовательность лексем,
- 2. *Datum-синтаксис*, сформулированный в терминах лексического синтаксиса, структурирующий последовательность лексем в виде последовательности *синтаксических данных*, где синтаксический datum является рекурсивно структурированным элементом,
- 3. *Программный синтаксис*, сформулированный в терминах синтаксиса считывания, задающий дальнейшую структуру и наполняющий смысловым содержанием синтаксические данные.

Синтаксические данные (называемые также внешними представлениями) одновременно служат как формой записи объектов, так и библиотекой Scheme (rnrs io ports (6)) (секция библиотек ??), предоставляющей процедуры get-datum и put-datum для чтения и записи синтаксических данных, преобразовывающие их из текстового представления в соответствующие объекты, и наоборот. Каждый синтаксический datum представляет соответствующее datum-значение. Синтаксический datum может использоваться в программе для получения соответствующего datum-значения с помощью quote (см. секцию 11.4.1).

Исходный текст Scheme состоит из синтаксических данных и (незначащих) комментариев. Синтаксические данные в исходном тексте Scheme называются формами. (Форма, вложенная в другую форму, называется подформой.) Следовательно, синтаксис Scheme обладает свойством, что любая последовательность символов, являющаяся формой, является также и синтаксическим datum, представляющей некоторый объект. Это может привести к замешательству, так как из контекста может быть не ясно, предназначена ли данная последовательность символов для представления объектов или текста программы. Это - также источник мощи, так как это облегчает написание программ, типа интерпретаторов или компиляторов, интерпретирующих программы в качестве объектов (или наоборот).

Ратит-значение может иметь несколько разных внешних представлений. Например, и "#e28.000", и "#x1c" являются синтаксическими данными, представляющими точный целый объект 28, а синтаксические данные "(8 13)", "(08 13)", "(8 . (13 . ()))" представляют список, содержащий точные целые объекты 8 и 13. Синтаксические данные, представляющие равные объекты (в смысле equal?; см. секцию 11.5), всегда эквивалентны как формы программы.

Вследствие точного соответствия синтаксических данных и datum-значений в данной работе термин *datum* иногда используется и для синтаксического datum, и для datum-значения, когда точный смысл очевиден из контекста.

Реализация никогда не должна расширять лексический или datum-синтаксис, за одним исключением: она не должна интерпретировать синтаксис #! (identifier), для любого (identifier) (см. секцию 4.2.4), который не r6rs, как нарушение синтаксиса, и она может использовать специфические #!-ргеfixed идентификаторы как флаги, указывающие, что последующий вход содержит расширения к лексическому стандарту или datum-синтаксису. Синтаксис #!r6rs может использоваться, чтобы показать, что вход позже написан с лексическим и datum-синтаксисом, описанным в данной работе. #!r6rs иначе интерпретируется как комментарий; см. секцию 4.2.3.

4.1. Нотапия

Формальный синтаксис Scheme записан в расширенном BNF. Нетерминальные символы записаны с помощью угловых скобок. Регистр является незначащим для нетерминальных имён.

Все пробелы в грамматике применяются для удобочитаемости. (Empty) обозначает пустую строку.

Для более краткого описания используются следующие расширения BNF: $\langle \text{thing} \rangle^*$ означает ноль или больше возникновений $\langle \text{thing} \rangle$, а $\langle \text{thing} \rangle^+$ означает по крайней мере один $\langle \text{thing} \rangle$.

Некоторые нетерминальные имена относятся к скалярным значениям Unicode того же самого имени: (U+0009), (character tabulation) (linefeed) (U+000A), (carriage return) (U+000D), (line tabulation) (U+000B). (form feed) (U+000C). ⟨carriage return⟩ (U+000D). $\langle \text{space } (\text{U}+0020) \rangle$, $\langle \text{next line} \rangle$ (U+0085), (line separator) (U+2028) и (paragraph separator) (U+2029).

4.2. Лексический синтаксис

Лексический синтаксис определяет, как символьная последовательность разбивается на последовательность лексем, пропуская незначащие части, типа комментариев и пробелов. Полагается, что символьная последовательность является текстом согласно стандарту Unicode [?]. Некоторые из лексем, типа идентификаторов, представлений числовых

объектов, строки и т.д., лексического синтаксиса являются синтаксическими данными в datum-синтаксисе и, таким образом, представляют объекты. Помимо формального описания синтаксиса, в этой секции также описывается, какие datum-значения представляют эти синтаксические данные.

Лексический синтаксис в описании комментариев содержит прямую ссылку на $\langle datum \rangle$, описанную как часть datum-синтаксиса. Будучи комментариями, однако, такие $\langle datum \rangle$ не играют существенную роль в синтаксисе.

Регистр является значащим, за исключением представлений booleans, числовых объектов и шестнадцатеричных чисел, определяющих скалярные значения Unicode. Например, **#x1a** и **#x1a** эквивалентны. А вот идентификатор **Foo** отличается от идентификатора **FOO**.

4.2.1. Формальное описание

(Interlexeme space) может находиться с любой стороны лексемы, но не внутри лексемы

⟨Identifier⟩, ., ⟨number⟩, ⟨character⟩ и ⟨boolean⟩ могут заканчиваться ⟨delimiter⟩ или концом ввода.

Следующие два знака зарезервированы для будущих расширений языка: {

```
⟨lexeme⟩ → ⟨identifier⟩ | ⟨boolean⟩ | ⟨number⟩
         ⟨character⟩ | ⟨string⟩
         ( | ) | [ | ] | #( | #vu8( | ' | \square | , | , @ | .
        #' | #□ | #, | #,@
\langle delimiter \rangle \longrightarrow ( | ) | [ | ] | " | ; | #
      | \langle whitespace \rangle
⟨whitespace⟩ → ⟨character tabulation⟩
         ⟨linefeed⟩ | ⟨line tabulation⟩ | ⟨form feed⟩
         ⟨carriage return⟩ | ⟨next line⟩
         (any character whose category is Zs, Zl, or Zp)
\langle \text{line ending} \rangle \longrightarrow \langle \text{linefeed} \rangle \mid \langle \text{carriage return} \rangle
         ⟨carriage return⟩ ⟨linefeed⟩ | ⟨next line⟩
        ⟨carriage return⟩ ⟨next line⟩ | ⟨line separator⟩
\langle comment \rangle \longrightarrow ; \langle all subsequent characters up to a
                               ⟨line ending⟩ or ⟨paragraph separator⟩⟩
         ⟨nested comment⟩
         #; (interlexeme space) (datum)
        #!r6rs
\langle nested \ comment \rangle \longrightarrow \# | \langle comment \ text \rangle
                                         ⟨comment cont⟩* |#
\langle comment text \rangle \longrightarrow \langle character sequence not containing \rangle
                                # | or | # \
\langle comment cont \rangle \longrightarrow \langle nested comment \rangle \langle comment text \rangle
\langle atmosphere \rangle \longrightarrow \langle whitespace \rangle \mid \langle comment \rangle
\langle \text{interlexeme space} \rangle \longrightarrow \langle \text{atmosphere} \rangle^*
⟨identifier⟩ → ⟨initial⟩ ⟨subsequent⟩*
      | (peculiar identifier)
\langle \text{initial} \rangle \longrightarrow \langle \text{constituent} \rangle \mid \langle \text{special initial} \rangle
      | (inline hex escape)
\langle letter \rangle \longrightarrow a \mid b \mid c \mid \dots \mid z
      | A | B | C | ... | Z
\langle constituent \rangle \longrightarrow \langle letter \rangle
```

| \(\langle\) any character whose Unicode scalar value is greater than 127, and whose category is Lu, Ll, Lt, Lm, Lo, Mn, Nl, No, Pd, Pc, Po, Sc, Sm, Sk, So, or Co\)

```
\langle \text{special initial} \rangle \longrightarrow ! \mid \$ \mid \$ \mid \& \mid * \mid / \mid : \mid < \mid = \langle \text{prefix } R \rangle \longrightarrow \langle \text{radix } R \rangle \langle \text{exactness} \rangle
      | > | ? | ^ | | ~
\langle \text{subsequent} \rangle \longrightarrow \langle \overline{\text{initial}} \rangle \mid \langle \text{digit} \rangle
         (any character whose category is Nd, Mc, or Me)
          (special subsequent)
\langle digit \rangle \longrightarrow 0 \mid 1 \mid 2 \mid 3 \mid 4 \mid 5 \mid 6 \mid 7 \mid 8 \mid 9
⟨hex digit⟩ → ⟨digit⟩
       | a | A | b | B | c | C | d | D | e | E | f | F
\langle \text{special subsequent} \rangle \longrightarrow + | - | . | @
\langle \text{inline hex escape} \rangle \longrightarrow \langle \text{kex scalar value} \rangle;
\langle \text{hex scalar value} \rangle \longrightarrow \langle \text{hex digit} \rangle^+
\langle peculiar identifier \rangle \longrightarrow + | - | \dots | -> \langle subsequent \rangle^*
⟨boolean⟩ → #t | #T | #f | #F
⟨character⟩ → #\⟨any character⟩
        #\\character name\
       | #\x{hex scalar value}
⟨character name⟩ → nul | alarm | backspace | tab
         linefeed | newline | vtab | page | return
        esc | space | delete
\langle \text{string} \rangle \longrightarrow \text{"} \langle \text{string element} \rangle * \text{"} \langle \text{string element} \rangle \longrightarrow \langle \text{any character other than " or } \rangle
          \a | \b | \t | \n | \v | \f | \r
         \" | \\
        \\langle\intraline\text{whitespace}\langle\line\text{ending}\
                     (intraline whitespace)
        (inline hex escape)
⟨intraline whitespace⟩ → ⟨character tabulation⟩
      \ \langle any character whose category is Zs\
```

A (hex scalar value) represents a Unicode scalar value between 0 and #x10FFFF, excluding the range [#xD800, #xDFFF].

The rules for $\langle \text{num } R \rangle$, $\langle \text{complex } R \rangle$, $\langle \text{real } R \rangle$, $\langle \text{ureal } R \rangle$, (uinteger R), and (prefix R) below should be replicated for R = 2, 8, 10, and 16. There are no rules for $\langle \text{decimal } 2 \rangle$, (decimal 8), and (decimal 16), which means that number representations containing decimal points or exponents must be in decimal radix.

```
\langle \text{number} \rangle \longrightarrow \langle \text{num } 2 \rangle \mid \langle \text{num } 8 \rangle
              |\langle \text{num } 10 \rangle| \langle \text{num } 16 \rangle
\langle \text{num } R \rangle \longrightarrow \langle \text{prefix } R \rangle \langle \text{complex } R \rangle
\langle \operatorname{complex} R \rangle \longrightarrow \langle \operatorname{real} R \rangle \mid \langle \operatorname{real} R \rangle \otimes \langle \operatorname{real} R \rangle
                     \langle \operatorname{real} R \rangle + \langle \operatorname{ureal} R \rangle i | \langle \operatorname{real} R \rangle - \langle \operatorname{ureal} R \rangle i
                      \langle \operatorname{real} R \rangle + \langle \operatorname{naninf} \rangle i | \langle \operatorname{real} R \rangle - \langle \operatorname{naninf} \rangle i
                      \langle \operatorname{real} R \rangle + i | \langle \operatorname{real} R \rangle - i
                    + \langle \operatorname{ureal} R \rangle i | - \langle \operatorname{ureal} R \rangle i
                   + \langle naninf \rangle i | - \langle naninf \rangle i
                 + i | - i
\langle \operatorname{real} R \rangle \longrightarrow \langle \operatorname{sign} \rangle \langle \operatorname{ureal} R \rangle
| + \langle naninf \rangle | - \langle naninf \rangle
\langle naninf \rangle \longrightarrow nan.0 | inf.0
\langle \operatorname{ureal} R \rangle \longrightarrow \langle \operatorname{uinteger} R \rangle
                      \langle \text{uinteger } R \rangle / \langle \text{uinteger } R \rangle
                      \langle \operatorname{decimal} R \rangle \langle \operatorname{mantissa} \operatorname{width} \rangle
\langle \text{decimal } 10 \rangle \longrightarrow \langle \text{uinteger } 10 \rangle \langle \text{suffix} \rangle
                    . \langle \text{digit } 10 \rangle^+ \langle \text{suffix} \rangle
\langle \text{digit } 10 \rangle^+ . \langle \text{digit } 10 \rangle^* \langle \text{suffix} \rangle
\langle \text{digit } 10 \rangle^+ . \langle \text{suffix} \rangle
```

```
\langle \text{uinteger } R \rangle \longrightarrow \langle \text{digit } R \rangle^+
          |\langle exactness \rangle \langle radix R \rangle
\langle suffix \rangle \longrightarrow \langle empty \rangle
          |\langle \text{exponent marker} \rangle \langle \text{sign} \rangle \langle \text{digit } 10 \rangle^+
\langle \text{exponent marker} \rangle \longrightarrow \text{e} \mid \text{E} \mid \text{s} \mid \text{S} \mid \text{f} \mid \text{F}
          | d | D | 1 | L
\langle mantissa \ width \rangle \longrightarrow \langle empty \rangle
           | | \langle \text{digit } 10 \rangle^+
\langle \text{sign} \rangle \longrightarrow \langle \text{empty} \rangle \mid + \mid -
\langle \text{exactness} \rangle \longrightarrow \langle \text{empty} \rangle
          | #i | #I | #e | #E
\langle \operatorname{radix} 2 \rangle \longrightarrow \#b \mid \#B
\langle radix 8 \rangle \longrightarrow \#0 \mid \#0
\langle radix 10 \rangle \longrightarrow \langle empty \rangle \mid \#d \mid \#D
\langle radix 16 \rangle \longrightarrow \#x \mid \#x
\langle \text{digit } 2 \rangle \longrightarrow 0 \mid 1
\langle \operatorname{digit} 8 \rangle \longrightarrow 0 \mid 1 \mid 2 \mid 3 \mid 4 \mid 5 \mid 6 \mid 7
\langle \text{digit } 10 \rangle \longrightarrow \langle \text{digit} \rangle
\langle \text{digit } 16 \rangle \longrightarrow \langle \text{hex digit} \rangle
```

4.2.2. Окончание строки

В Scheme окончание строки является значащим в однострочных комментариях (см. секцию 4.2.3) и внутри строковых литералов. В исходном тексте Scheme любое окончание строки в (line ending) означает конец строки. Кроме того, двухсимвольное окончание строки (carriage return) (linefeed) и (carriage return) (next line) считается одним окончанием строки.

В строковом литерале (line ending) без \ перед ним обозначает символ linefeed, являющийся стандартным символом конца строки Scheme.

4.2.3. Пробельные символы и комментарии

Пробельными символами являются пробелы, обратные переводы строк, переводы каретки, символы табуляции, переводы страницы, линейные табуляции и любой другой символ, категория которого - Zs, Zl, или Zp. Пробельные символы используются для улучшения удобочитаемости и при необходимости отделения лексем друг от друга. Пробельные символы могут находиться между любыми двумя лексемами, но не внутри лексемы. Пробельный символ может также находиться в строке, где он является значащим.

Лексический синтаксис включает несколько форм комментариев. Во всех случаях, комментарии невидимы, в Scheme, за исключением того, что они действуют как разделители, таким образом, например, комментарий не может находиться в середине идентификатора или представления числового объекта.

Точка с запятой (;), указывает начало строки комментария. Комментарий продолжается до конца строки, на которой находится точка с запятой.

Другим способом указания комментария является добавления к ⟨datum⟩ (см. секцию 4.3.1) префикса #;, возможно с ⟨interlexeme space⟩ перед ⟨datum⟩. Комментарий состоит из приставки комментария #; и ⟨datum⟩. Такая нотация полезна для "комментирования" секций кода.

Блоковые комментарии могут быть обозначены соответствующим образом вложенными парами #| и | #.

```
#|
   The FACT procedure computes the factorial
   of a non-negative integer.
|#
(define fact
   (lambda (n)
    ;; base case
    (if (= n 0)
        #; (= n 1)
        1     ; identity of *
        (* n (fact (- n 1))))))
```

Лексема **#!r6rs**, которая означает, что текст следующей далее программы написан с лексическим и dataсинтаксисом, описанным в данной работе, также иным образом интерпретируется как комментарий.

4.2.4. Идентификаторы

Большинство идентификаторов, допустимых в других языках программирования, также допустимы и в Scheme. В общем случае, последовательность букв, цифр, и "расширенных алфавитных символов" является идентификатором, если она начинается с символа, с которого не может начинаться представление числового объекта. Кроме того, идентификаторами являются +, - и ..., равно как и последовательность букв, цифр и расширенных алфавитных символов, начинающаяся с двухсимвольной последовательности ->. Некоторые примеры идентификаторов:

Расширенные алфавитные символы могут использоваться внутри идентификаторов, как если бы они были буквами. Расширенными алфавитными символами являются:

```
! $ % & * + - . / : < = > ? @ ^ ~
```

Кроме того, в идентификаторах могут использоваться все символы, чьи скалярные значения Unicode больше, чем 127, и чьей категорией Unicode является Lu, Ll, Lt, Lm, Lo, Mn, Mc, Me, Nd, Nl, No, Pd, Pc, Po, Sc, Sm, Sk, So, или Co. Кроме того, любой символ может использоваться в идентификаторе, если он специфицирован через \langle inline hex escape \rangle . Например, идентификатор $H\x65;110$ - точо такой же, как и идентификатор χ 3BB; - точно такой же, как и идентификатор χ

В программе Scheme любой идентификатор может использоваться как переменная или как синтаксическое ключевое словозупастіс keyword (см. секции 5.2 и 9.2). Любой идентификатор может также использоваться как синтаксический datum, в этом случае он представляет *символ* (см. секцию 11.10).

4.2.5. Booleans

Стандартные булевые объекты для true и false имеют внешние представления #t и #f.

4.2.6. Символы

Символы представляются с помощью нотации $\#\$ (character) или $\#\$ (character name) или $\#\$ (character value).

Например:

#\a #\A #\() #\\ #\\\ #\\\\ #\\\\\\\\\\\\\\\\ #\\\\\\	lower case letter a upper case letter A left parenthesis space character U+0000 U+0007 U+0008 U+0009 U+000A U+000A U+000B U+000C U+000D U+001B U+0020 preferred way to write a space U+007F U+00FF U+03BB U+6587 U+03BB
<pre>#\x0001z #\\x #\alarmx #\alarm x #\Alarm #\alert #\xA #\xFF #\xff #\xff #\x ff</pre>	&lexical exception &lexical exception &lexical exception U+0007 followed by x &lexical exception &lexical exception U+000A U+00FF U+00FF U+0078 followed by another datum, ff

U+0078 $\#\x(ff)$

followed by another datum,

a parenthesized ff

 $\# \setminus (x)$ &lexical exception #\(x &lexical exception

U+0028 #\((x)

followed by another datum,

parenthesized x

#\x00110000 &lexical exception

out of range

#\x000000001 U+0001

#\xD800 **&lexical** exception

in excluded range

(Примечание &lexical exception означает, что рассматриваемая строка является лексическим нарушением синтаксиca.)

Регистр является значащим в #\(character\) и в #\ (character name), но не в #\x (hex scalar value). За (character) должен находиться (delimeter) или конец ввода. Это правило разрешает различные неоднозначные случаи с участием названных символов, требуя, например, чтобы последовательность символов "#\space" интерпретировалась как символ пробела, а не как символ "#\s"и следующим за ним идентификатором "расе".

Note: Нотация #\newline сохранена с целью обратной совместимости. Её использование устарело; вместо неё должна использоваться #\linefeed.

4.2.7. Строки

Строка представляется последовательностью символов, окружённых двойными кавычками ("). Внутри стрового литерала различные управляющие последовательности представляют символы, кроме самих себя. Управляющие последовательности всегда начинаются с обратного слеша (\):

• \a : alarm, U+0007

• **\b**: backspace, U+0008

• \t : character tabulation, U+0009

• \n : linefeed, U+000A

• \v : line tabulation, U+000B

• \f: formfeed, U+000C

• \r : return, U+000D

• \": doublequote, U+0022

• \\ : backslash, U+005C

• \\(\langle\) intraline whitespace\(\rangle\) line ending\(\rangle\) (intraline whitespace): nothing

• \x \(\max\) hex scalar value\(\right\); specified character (note the terminating semi-colon).

Эти управляющие последовательности регистрочувствительны, за исключением того, что алфавитные цифры (hex scalar value) могут быть заглавными или строчными.

Любой другой символ в строке после обратного слеша является нарушением синтаксиса. За исключением окончания строки, любой символ в строковом литерале вне управляющей последовательностии, не являющийся двойными кавычками, обозначает самого себя. Например, односимвольный строковый литерал " λ " (двойные кавычки, строчная lambda, двойные кавычки) представляет ту же самую строку, как и "\x03bb;". Окончание строки, находящееся не за обратным слешем, обозначает символ linefeed.

Примеры:

"abc" "\x41;bc" "\x41; bc"	U+0061, U+0062, U+0063 "Abc"; U+0041, U+0062, U+0063 "A bc" U+0041, U+0020, U+0062, U+0063
"\x41bc;"	U+41BC
"\x41"	&lexical exception
"\x;"	&lexical exception
"\x41bx;"	<pre>&lexical exception</pre>
"\x00000041;"	"A" ; U+0041
"\x0010FFFF;"	U+10FFFF
"\x00110000;"	&lexical exception out of range
"\x00000001;"	U+0001
"\xD800;"	&lexical exception
	in excluded range
"A	-
bc"	U+0041, U+000A, U+0062, U+0063 if no space occurs after the A

4.2.8. Числа

Синтаксис внешних представлений числовых объектов формально описан правилом (number) формальной грамматики. Во внешних представлениях числовых объектов регистр является незначащим.

Представление числового объекта может быть записано в двоичном, восьмеричном, десятичном или шестнадцатеричном виде при помощи приставки основания. Приставками основания являются #b (двоичная), #о (восьмеричная), #d (десятичная) и #ж (шестнадцатеричная). Без приставки основания представление числового объекта предполагается выраженным в десятичном виде.

Представление числового объекта может указываться точным или неточным с помощью приставки. Приставками являются #е для точного и #і для неточного. Приставка точности может находиться до или после любой используемой приставки основания. Если представление числового объекта не содержит приставки точности, константа является неточной, если она содержит десятичную точку, экспоненту или непустую ширину мантиссы; в противном случае она является точной.

В системах с неточными числовыми объектами переменной точности может быть полезно определение точности константы. С этой целью представления числовых объектов могут записываться с экспоненциальным маркером, указывающим желаемую точность неточного представления. Буквы **s**, **f**, **d** и **1** указывают на использование точности short, single, double и long соответственно. (Если существует менее четырёх внутренних неточных представлений, четыре спецификации размера преобразовываются в доступные. Например, реализация с двумя внутренними представлениями может преобразовывать вместе short и single, а также long и double) Кроме того, маркер точности **e** указывает точность по умолчанию для реализации. Точность по умолчанию имеет значение по крайней мере не менее точности double, но реализации могут позволять пользователю устанавливать данное умолчание.

```
3.1415926535898F0
Round to single, perhaps 3.141593
0.6L0
Extend to long, perhaps .60000000000000
```

Представление числового объекта с непустой шириной мантиссы $x \mid p$ представляет наилучшее двоичное приближение с плавающей точкой x с помощью p-битной значащей части. Например, $\mathbf{1.1} \mid \mathbf{53}$ является представлением наилучшего приближения 1.1 в IEEE двойной точности. Если x является внешним представлением неточного действительного числового объекта, не содержащим вертикальной черты, его численное значение должно вычисляться так, как если бы оно имело ширину мантиссы $\mathbf{53}$ или более.

Реализации, использующие двоичные представления с плавающей точкой действительных числовых объектов, должны представлять $x \mid p$ с помощью p-битной значащей части, если это удобно, или с большей точностью, если p-битная значащая часть не удобна, или с наибольшей доступной точностью, если p или более бит значащей части не удобны в реализации.

Note: Точность значащей части не следует путать с количеством бит, используемых для представления значащей части. В стандартах IEEE с плавающей точкой, например, старший значащий бит значащей части является неявным при одинарной и двойной точности, и явным при расширенной точности. На математическую точность не влияет, является ли этот бит явным или неявным. В реализациях, использующих двоичную плавающую точку, точность по умолчанию может быть вычислена путём вызова следующей процедуры:

```
(define (precision)
  (do ((n 0 (+ n 1))
        (x 1.0 (/ x 2.0)))
        ((= 1.0 (+ 1.0 x)) n)))
```

Note: Если основным представлением с плавающей точкой является двойная точность IEEE, $\mid p$, суффикс не должен всегда быть пропущеным: Денормализованные числа с плавающей точкой имеют пониженную точность, и поэтому их внешние представления должны содержать суффикс $\mid p$ с фактической шириной значащей части.

Литералы **+inf.0** и **-inf.0** представляют положительную и отрицательную бесконечность соответственно. Ли-

терал +nan. 0 представляет NaN, являющийся результатом (/ 0.0 0.0), и может также представлять другие NaN.

Если x является внешним представлением неточного действительного числового объекта и не содержит вертикальной черты и экспоненциального маркера кроме \mathbf{e} , неточным действительным числовым объектом, представляющим его, является flonum (см. секцию библиотек $\mathbf{??}$). Некоторые или все другие внешние представления неточных действительных числовых объектов могут также представлять flonums, но это не является требованием данной работы.

4.3. Datum-синтаксис

Datum-синтаксис описывает синтаксис синтаксических данных в терминах последовательности (лексем) как определено в лексическом синтаксисе.

Синтаксические данные включают данные лексем, описанные в предыдущих секциях, а также следующие конструкции для формирования составных данных:

- пары и списки, заключённые в () или [] (см. секцию 4.3.2)
- векторы (см. секцию 4.3.3)
- байтовые векторы (см. секцию 4.3.4)

4.3.1. Формальное описание

Следующая грамматика описывает синтаксис синтаксических данных в терминах лексем различных видов, определённых в грамматике в секции 4.2:

```
\langle datum \rangle \longrightarrow \langle lexeme \ datum \rangle
         | (compound datum)
\langle lexeme \ datum \rangle \longrightarrow \langle boolean \rangle \mid \langle number \rangle
          | \langle character \rangle | \langle string \rangle | \langle symbol \rangle
\langle \text{symbol} \rangle \longrightarrow \langle \text{identifier} \rangle
\langle compound \ datum \rangle \longrightarrow \langle list \rangle \mid \langle vector \rangle \mid \langle bytevector \rangle
\langle list \rangle \longrightarrow (\langle datum \rangle^*) \mid [\langle datum \rangle^*]
            (\langle datum \rangle^+ \cdot \langle datum \rangle) \mid [\langle datum \rangle^+ \cdot \langle datum \rangle]
             (abbreviation)
\langle abbreviation \rangle \longrightarrow \langle abbrev \ prefix \rangle \langle datum \rangle
\langle \text{abbrev prefix} \rangle \longrightarrow ' \mid \Box \mid , \mid , @
          | #' | #□ | #, | #,@
\langle \text{vector} \rangle \longrightarrow \# (\langle \text{datum} \rangle^*)
\langle bytevector \rangle \longrightarrow \#vu8 (\langle u8 \rangle^*)
\langle u8 \rangle \longrightarrow \langle any \langle number \rangle representing an exact
                       integer in \{0, \ldots, 255\}
```

4.3.2. Пары и списки

Данные списков и пар, представляющие значения пар и списков (см. секцию 11.9), представляются с помощью круглых или квадратных скобок. Соответствие пар квадратных скобок, находящихся в правилах (list), эквивалентно соответствию пар круглых скобок.

Наиболее общей нотацией для пар Scheme как син-"точечная" таксических ланных является нотания $(\langle datum_1 \rangle . \langle datum_2 \rangle)$, где $\langle datum_1 \rangle$ является представлением значения саг, а $\langle datum_2 \rangle$ - значения поля cdr. Например, (4 . 5) является парой, car которой - 4, a cdr -

Для списков может использоваться более чёткая нотация: элементы списка просто заключаются в круглые скобки и разделяются пробелами. Пустой список представляется, как (). Например,

являются эквивалентными формами записи списка симво-

Общее правило гласит, что если за точкой следует открывающаяся круглая скобка, точка, открывающаяся круглая скобка и соответствующая ей закрывающаяся круглая скобка во внешнем представлении могут быть пропущены.

Последовательность символов "(4 . 5)" является внешним представлением пары, а не выражением, которое вычисляется как пара. Аналогично, последовательность символов "(+ 2 6)" не является внешним представлением целого числа 8, даже при том, что она является выраженим (на языке библиотеки (rnrs base (6)), вычисляемым как целое число 8; наоборот, это синтаксический datum, представляющий трёхэлементный список, элементами которого являются символ + и целые числа 2 и 6.

4.3.3. Векторы

Векторные данные, представляющие вектора объектов (см. секцию 11.13), представляются с помощью нотации # ((datum) ...) . Например, вектор с длиной 3, содержащий числовой объект для нуля в элементе 0, список (2 2 2 2) в элементе 1 и строку "Анна" в элементе 2, может быть представлен следующим образом:

Это внешнее представление вектора, а не выражение, вычисляемое как вектор.

4.3.4. Байтовые векторы

Байт-векторные данные, представляющие байтовые вектора (см. библиотечную главу ??), представляются с помощью нотации **#vu8** ($\langle u8 \rangle$...), где $\langle u8 \rangle$ представляет октет байтового вектора. Например, байтовый вектор с длиной 3, содержащий октеты 2, 24 и 123, может быть представлен следующим образом:

Это внешнее представление байтового вектора, а не выражение, вычисляемое как байтовый вектор.

4.3.5. Сокращения

' ⟨datum⟩

```
\Box \langle datum \rangle
, (datum)
, @ (datum)
#' (datum)
#□⟨datum⟩
#, \datum
# , @ (datum)
Каждый из них является сокращением:
' (datum) for (quote (datum)),
\Box \langle datum \rangle for (quasiquote \langle datum \rangle),
, \langle datum \rangle for (unquote \langle datum \rangle),
, @⟨datum⟩ for (unquote-splicing ⟨datum⟩),
```

Семантические концепции

#, $\langle datum \rangle$ for (unsyntax $\langle datum \rangle$), and

#, @ (datum) for (unsyntax-splicing (datum)).

#' (datum) for (syntax (datum)), $\#\Box\langle datum\rangle$ for (quasisyntax $\langle datum\rangle$),

5.1. Программы и библиотеки

Программа Scheme состоит из программы верхнего уровня совместно с набором библиотек, каждая из которых определяет часть программы, связанную с другими частями посредством явно указываемых экспорта и импорта. Библиотека состоит из ряда спецификаций экспорта и импорта, а также тела, состоящего из определений и выражений. Программа верхнего уровня похожа на библиотеку, но не имеет спецификаций экспорта. В главах 7 и 8 описаны синтаксис и семантика библиотек и программ верхнего уровня соответственно. В главе 11 описана основная библиотека, в которой определено большинство конструкций, традиционно ассоциированных со Scheme. В отдельной работе [?] описаны различные стандартные библиотеки, предоставляемые системой Scheme.

Деление на основную библиотеку и прочие стандартные библиотеки является прикладным, а не конструктивным. В частности, некоторые средства, обычно реализуемые как "примитивы" компилятором или системой во время выполнения, а не в терминах других стандартных процедур или синтаксических форм, не являются частью основной библиотеки, а определены в отдельных библиотеках. Примеры включают библиотеки fixnums и flonums, библиотеки исключений и условий, а также библиотеки для записей.

5.2. Переменные, ключевые слова и регионы

В теле библиотеки или программы верхнего уровня идентификатор может именовать или вид синтаксиса, или ячейку памяти, где может храниться значение. Идентификатор, именующий вид синтаксиса, называется ключевым словом,

или синтаксическим ключевым словом, и считается привязанным к этому виду синтаксиса (или, в случае синтаксической абстракции, преобразователем, транслирующим синтаксис в более примитивные формы; см. секцию 9.2). Идентификатор, именующий ячейку памяти, называется переменной и считается привязанным к этой ячейке памяти. К каждой точке программы верхнего уровня или библиотеке привязана определённая, специфическая совокупность идентификаторов. Совокупность таких идентификаторов, совокупность видимого связывания, называется окружением, действующим в данной точке.

Одни формы используются для создания синтаксических абстракций и связывания ключевых слов с преобразователями для этих новых синтаксических абстракций, в то время как другие формы создают новые ячейки памяти и связывают переменные с этими ячейками. Все эти формы в совокупности называются конструкциями привязки., Некоторые конструкции привязки принимают форму определений, в то время как другие являются выражениями. За исключением экспортируемых библиотечных привязок, привязка, созданная определением, видима только внутри тела, в котором находится определение, например, в теле библиотеки, в программе верхнего уровня, или в выражение **lambda**. Экспортируемые библиотечные привязки также видимы внутри тел библиотек и программ верхнего уровня, импортирующих их (см. главу 7).

Выражения, связывающие переменные, включают формы lambda, let, let*, letrec, letrec*, let-values, M let*-values из основной библиотеки (см. секции 11.4.2, 11.4.6). Из них **lambda** является самой фундаментальной. Определения переменных, находящиеся внутри тела такого выражения, или внутри тела библиотеки или программы верхнего уровня, интерпретируются как набор привязок letrec*. Кроме того, для тел библиотеки, к переменным, экспортируемым из библиотеки, можно обратиться, импортируя программы верхнего уровня и библиотеки.

Expressions that bind keywords include the let-syntax and letrec-syntax forms (see section 11.18). A define form (see section 11.2.1) is a definition that creates a variable binding (see section 11.2), and a define-syntax form is a definition that creates a keyword binding (see section 11.2.2).

Scheme is a statically scoped language with block structure. To each place in a top-level program or library body where an identifier is bound there corresponds a region of code within which the binding is visible. The region is determined by the particular binding construct that establishes the binding; if the binding is established by a lambda expression, for example, then its region is the entire lambda expression. Every mention of an identifier refers to the binding of the identifier that establishes the innermost of the regions containing the use. If a use of an identifier appears in a place where none of the surrounding expressions contains a binding for the identifier. the use may refer to a binding established by a definition or import at the top of the enclosing library or top-level program (see chapter 7). If there is no binding for the identifier, it is said to be unbound.

5.3. Exceptional situations

A variety of exceptional situations are distinguished in this report, among them violations of syntax, violations of a procedure's specification, violations of implementation restrictions, and exceptional situations in the environment. When an exceptional situation is detected by the implementation, an exception is raised, which means that a special procedure called the current exception handler is called. A program can also raise an exception, and override the current exception handler; see library section ??.

When an exception is raised, an object is provided that describes the nature of the exceptional situation. The report uses the condition system described in library section ?? to describe exceptional situations, classifying them by condition types.

Some exceptional situations allow continuing the program if the exception handler takes appropriate action. The corresponding exceptions are called *continuable*. For most of the exceptional situations described in this report, portable programs cannot rely upon the exception being continuable at the place where the situation was detected. For those exceptions, the exception handler that is invoked by the exception should not return. In some cases, however, continuing is permissible, and the handler may return. See library section ??.

Implementations must raise an exception when they are unable to continue correct execution of a correct program due to some implementation restriction. For example, an implementation that does not support infinities must raise an exception with condition type &implementation-restriction when it evaluates an expression whose result would be an infinity.

Some possible implementation restrictions such as the lack of representations for NaNs and infinities (see section 11.7.2) are anticipated by this report, and implementations typically must raise an exception of the appropriate condition type if they encounter such a situation.

This report uses the phrase "an exception is raised" synonymously with "an exception must be raised". This report uses the phrase "an exception with condition type t" to indicate that the object provided with the exception is a condition object of the specified type. The phrase "a continuable exception is raised" indicates an exceptional situation that permits the exception handler to return.

5.4. Argument checking

Many procedures specified in this report or as part of a standard library restrict the arguments they accept. Typically, a procedure accepts only specific numbers and types of arguments. Many syntactic forms similarly restrict the values to which one or more of their subforms can evaluate. These restrictions imply responsibilities for both the programmer and the implementation. Specifically, the programmer is responsible for ensuring that the values indeed adhere to the restrictions described in the specification. The implementation must check that the restrictions in the specification are indeed met, to the extent that it is reasonable, possible, and necessary to allow the specified operation to complete successfully. The implementation's responsibilities are specified in more detail in chapter 6 and throughout the report.

Note that it is not always possible for an implementation to completely check the restrictions set forth in a specification. For example, if an operation is specified to accept a procedure with specific properties, checking of these properties is undecidable in general. Similarly, some operations accept both lists and procedures that are called by these operations. Since lists can be mutated by the procedures through the (rnrs mutablepairs (6)) library (see library chapter ??), an argument that is a list when the operation starts may become a non-list during the execution of the operation. Also, the procedure might escape to a different continuation, preventing the operation from performing more checks. Requiring the operation to check that the argument is a list after each call to such a procedure would be impractical. Furthermore, some operations that accept lists only need to traverse these lists partially to perform their function; requiring the implementation to traverse the remainder of the list to verify that all specified restrictions have been met might violate reasonable performance assumptions. For these reasons, the programmer's obligations may exceed the checking obligations of the implementation.

When an implementation detects a violation of a restriction for an argument, it must raise an exception with condition type &assertion in a way consistent with the safety of execution as described in section 5.6.

5.5. Syntax violations

The subforms of a special form usually need to obey certain syntactic restrictions. As forms may be subject to macro expansion, which may not terminate, the question of whether they obey the specified restrictions is undecidable in general.

When macro expansion terminates, however, implementations must detect violations of the syntax. A syntax violation is an error with respect to the syntax of library bodies, top-level bodies, or the "syntax" entries in the specification of the base library or the standard libraries. Moreover, attempting to assign to an immutable variable (i.e., the variables exported by a library; see section 7.1) is also considered a syntax violation.

If a top-level or library form in a program is not syntactically correct, then the implementation must raise an exception with condition type &syntax, and execution of that top-level program or library must not be allowed to begin.

5.6. Safety

The standard libraries whose exports are described by this document are said to be safe libraries. Libraries and top-level programs that import only from safe libraries are also said to be safe.

As defined by this document, the Scheme programming language is safe in the following sense: The execution of a safe top-level program cannot go so badly wrong as to crash or to continue to execute while behaving in ways that are inconsistent with the semantics described in this document, unless an exception is raised.

Violations of an implementation restriction must raise an exception with condition type &implementationrestriction, as must all violations and errors that would otherwise threaten system integrity in ways that might result in execution that is inconsistent with the semantics described in this document.

The above safety properties are guaranteed only for top-level programs and libraries that are said to be safe. In particular, implementations may provide access to unsafe libraries in ways that cannot guarantee safety.

5.7. Boolean values

Although there is a separate boolean type, any Scheme value can be used as a boolean value for the purpose of a conditional test. In a conditional test, all values count as true in such a test except for #f. This report uses the word "true" to refer to any Scheme value except #f, and the word "false" to refer to #f.

5.8. Multiple return values

A Scheme expression can evaluate to an arbitrary finite number of values. These values are passed to the expression's continuation.

Not all continuations accept any number of values. For example, a continuation that accepts the argument to a procedure call is guaranteed to accept exactly one value. The effect of passing some other number of values to such a continuation is unspecified. The call-with-values procedure described in section 11.15 makes it possible to create continuations that accept specified numbers of return values. If the number of return values passed to a continuation created by a call to call-with-values is not accepted by its consumer that was passed in that call, then an exception is raised. A more complete description of the number of values accepted by different continuations and the consequences of passing an unexpected number of values is given in the description of the values procedure in section 11.15.

A number of forms in the base library have sequences of expressions as subforms that are evaluated sequentially, with the return values of all but the last expression being discarded. The continuations discarding these values accept any number of values.

5.9. Unspecified behavior

If an expression is said to "return unspecified values", then the expression must evaluate without raising an exception, but the values returned depend on the implementation; this report explicitly does not say how many or what values should be returned. Programmers should not rely on a specific number of return values or the specific values themselves.

5.10. Storage model

Variables and objects such as pairs, vectors, bytevectors, strings, hashtables, and records implicitly refer to locations or sequences of locations. A string, for example, contains as many locations as there are characters in the string. (These locations need not correspond to a full machine word.) A new value may be stored into one of these locations using the string-set! procedure, but the string contains the same locations as before.

An object fetched from a location, by a variable reference or by a procedure such as car, vector-ref, or string-ref, is equivalent in the sense of eqv? (section 11.5) to the object last stored in the location before the fetch.

Every location is marked to show whether it is in use. No variable or object ever refers to a location that is not in use. Whenever this report speaks of storage being allocated for a variable or object, what is meant is that an appropriate number of locations are chosen from the set of locations that are not in use, and the chosen locations are marked to indicate that they are now in use before the variable or object is made to refer to them.

It is desirable for constants (i.e. the values of literal expressions) to reside in read-only memory. To express this, it is convenient to imagine that every object that refers to locations is associated with a flag telling whether that object is mutable or immutable. Literal constants, the strings returned by symbol->string, records with no mutable fields, and other values explicitly designated as immutable are immutable objects, while all objects created by the other procedures listed in this report are mutable. An attempt to store a new value into a location referred to by an immutable object should raise an exception with condition type &assertion.

5.11. Proper tail recursion

Implementations of Scheme must be *properly tail-recursive*. Procedure calls that occur in certain syntactic contexts called *tail contexts* are *tail calls*. A Scheme implementation is properly tail-recursive if it supports an unbounded number of active tail calls. A call is *active* if the called procedure may still return. Note that this includes regular returns as well as returns through continuations captured earlier by call-with-current-continuation that are later invoked. In the absence of captured continuations, calls could return at most once and the active calls would be those that had not yet returned. A formal definition of proper tail recursion can be found in Clinger's paper [?]. The rules for identifying tail calls in constructs from the (rnrs base (6)) library are described in section 11.20.

5.12. Dynamic extent and the dynamic environment

For a procedure call, the time between when it is initiated and when it returns is called its *dynamic extent*. In Scheme, call-with-current-continuation (section 11.15) allows reentering a dynamic extent after its procedure call has returned. Thus, the dynamic extent of a call may not be a single, connected time period.

Some operations described in the report acquire information in addition to their explicit arguments from the dynamic example, call-with-currentenvironment. For continuation accesses an implicit context established by dynamic-wind (section 11.15), and the raise procedure (library section ??) accesses the current exception handler. The operations that modify the dynamic environment do so dynamically, for the dynamic extent of a call to a procedure like dynamic-wind or with-exception-handler. When such a call returns, the previous dynamic environment is restored. The dynamic environment can be thought of as part of the dynamic extent of a call. Consequently, it is captured by call-with-current-continuation, and restored by invoking the escape procedure it creates.

6. Entry format

The chapters that describe bindings in the base library and the standard libraries are organized into entries. Each entry describes one language feature or a group of related features, where a feature is either a syntactic construct or a built-in procedure. An entry begins with one or more header lines of the form

template category

The *category* defines the kind of binding described by the entry, typically either "syntax" or "procedure". An entry may specify various restrictions on subforms or arguments. For background on this, see section 5.4.

6.1. Syntax entries

If *category* is "syntax", the entry describes a special syntactic construct, and the template gives the syntax of the forms of the construct. The template is written in a notation similar to a right-hand side of the BNF rules in chapter 4, and describes the set of forms equivalent to the forms matching the template as syntactic data. Some "syntax" entries carry a suffix (expand), specifying that the syntactic keyword of the construct is exported with level 1. Otherwise, the syntactic keyword is exported with level 0; see section 7.2.

Components of the form described by a template are designated by syntactic variables, which are written using angle brackets, for example, ⟨expression⟩, ⟨variable⟩. Case is insignificant in syntactic variables. Syntactic variables stand for other forms, or sequences of them. A syntactic variable may refer to a non-terminal in the grammar for syntactic data (see section 4.3.1), in which case only forms matching that non-terminal are

permissible in that position. For example, (identifier) stands for a form which must be an identifier. Also, (expression) stands for any form which is a syntactically valid expression. Other nonterminals that are used in templates are defined as part of the specification.

The notation

```
\langle \text{thing}_1 \rangle \dots
```

indicates zero or more occurrences of a (thing), and

$$\langle \text{thing}_1 \rangle \langle \text{thing}_2 \rangle \dots$$

indicates one or more occurrences of a (thing).

It is the programmer's responsibility to ensure that each component of a form has the shape specified by a template. Descriptions of syntax may express other restrictions on the components of a form. Typically, such a restriction is formulated as a phrase of the form " $\langle x \rangle$ must be a ...". Again, these specify the programmer's responsibility. It is the implementation's responsibility to check that these restrictions are satisfied, as long as the macro transformers involved in expanding the form terminate. If the implementation detects that a component does not meet the restriction, an exception with condition type &syntax is raised.

6.2. Procedure entries

If *category* is "procedure", then the entry describes a procedure, and the header line gives a template for a call to the procedure. Parameter names in the template are italicized. Thus the header line

```
(vector-ref vector k)
                                            procedure
```

indicates that the built-in procedure vector-ref takes two arguments, a vector vector and an exact non-negative integer object k (see below). The header lines

$$(make-vector k)$$
 procedure $(make-vector k fill)$ procedure

indicate that the make-vector procedure takes either one or two arguments. The parameter names are case-insensitive: Vector is the same as vector.

As with syntax templates, an ellipsis ... at the end of a header line, as in

$$(= z_1 \ z_2 \ z_3 \ \dots)$$
 procedure

indicates that the procedure takes arbitrarily many arguments of the same type as specified for the last parameter name. In this case, = accepts two or more arguments that must all be complex number objects.

A procedure that detects an argument that it is not specified to handle must raise an exception with condition type &assertion. Also, the argument specifications are exhaustive: if the number of arguments provided in a procedure call does not match any number of arguments accepted by the procedure, an exception with condition type &assertion must be raised.

For succinctness, the report follows the convention that if a parameter name is also the name of a type, then the corresponding argument must be of the named type. For example, the header line for vector-ref given above dictates that the first argument to vector-ref must be a vector. The following naming conventions imply type restrictions:

obj	any object
\boldsymbol{z}	complex number object
x	real number object
y	real number object
q	rational number object
n	integer object
k	exact non-negative integer object
bool	boolean (#f or #t)
octet	exact integer object in $\{0, \dots, 255\}$
byte	exact integer object in $\{-128, \dots, 127\}$
char	character (see section 11.11)
pair	pair (see section 11.9)
vector	vector (see section 11.13)
string	string (see section 11.12)
condition	condition (see library section ??)
bytevector	bytevector (see library chapter ??)
proc	procedure (see section 1.6)
1	1 /

Other type restrictions are expressed through parameter-naming conventions that are described in specific chapters. For example, library chapter ?? uses a number of special parameter variables for the various subsets of the numbers.

With the listed type restrictions, it is the programmer's responsibility to ensure that the corresponding argument is of the specified type. It is the implementation's responsibility to check for that type.

A parameter called *list* means that it is the programmer's responsibility to pass an argument that is a list (see section 11.9). It is the implementation's responsibility to check that the argument is appropriately structured for the operation to perform its function, to the extent that this is possible and reasonable. The implementation must at least check that the argument is either an empty list or a pair.

Descriptions of procedures may express other restrictions on the arguments of a procedure. Typically, such a restriction is formulated as a phrase of the form "x must be a ..." (or otherwise using the word "must").

6.3. Implementation responsibilities

In addition to the restrictions implied by naming conventions, an entry may list additional explicit restrictions. These explicit restrictions usually describe both the programmer's responsibilities, who must ensure that the subforms of a form are appropriate, or that an appropriate argument is passed. and the implementation's responsibilities, which must check that subform adheres to the specified restrictions (if macro expansion terminates), or if the argument is appropriate. A description may explicitly list the implementation's responsibilities for some arguments or subforms in a paragraph labeled "Implementation responsibilities". In this case, the responsibilities specified for these subforms or arguments in the rest of the description are only for the programmer. A paragraph describing implementation responsibility does not affect the implementation's responsibilities for checking subforms or arguments not mentioned in the paragraph.

6.4. Other kinds of entries

If *category* is something other than "syntax" and "procedure", then the entry describes a non-procedural value, and the *category* describes the type of that value. The header line

indicates that &who is a condition type. The header line

indicates that unquote is a syntax binding that may occur only as part of specific surrounding expressions. Any use as an independent syntactic construct or identifier is a syntax violation. As with "syntax" entries, some "auxiliary syntax" entries carry a suffix (expand), specifying that the syntactic keyword of the construct is exported with level 1.

6.5. Equivalent entries

The description of an entry occasionally states that it is *the same* as another entry. This means that both entries are equivalent. Specifically, it means that if both entries have the same name and are thus exported from different libraries, the entries from both libraries can be imported under the same name without conflict.

6.6. Evaluation examples

The symbol "\iff " used in program examples can be read "evaluates to". For example,

means that the expression (* 5 8) evaluates to the object 40. Or, more precisely: the expression given by the sequence of characters "(* 5 8)" evaluates, in an environment that imports the relevant library, to an object that may be represented externally by the sequence of characters "40". See section 4.3 for a discussion of external representations of objects.

The "\iff symbol is also used when the evaluation of an expression causes a violation. For example,

means that the evaluation of the expression (integer->char #xD800) must raise an exception with condition type &assertion.

Moreover, the "\iffty" symbol is also used to explicitly say that the value of an expression in unspecified. For example:

$$(eqv? """") \implies unspecified$$

Mostly, examples merely illustrate the behavior specified in the entry. In some cases, however, they disambiguate otherwise ambiguous specifications and are thus normative. Note that, in some cases, specifically in the case of inexact number objects, the return value is only specified conditionally or approximately. For example:

(atan -inf.0)
$$\implies$$
 -1.5707963267948965 ; approximately

6.7. Naming conventions

By convention, the names of procedures that store values into previously allocated locations (see section 5.10) usually end in

By convention, "->" appears within the names of procedures that take an object of one type and return an analogous object of another type. For example, list->vector takes a list and returns a vector whose elements are the same as those of the list.

By convention, the names of predicates—procedures that always return a boolean value-end in "?" when the name contains any letters; otherwise, the predicate's name does not end with a question mark.

By convention, the components of compound names are separated by "-" In particular, prefixes that are actual words or can be pronounced as though they were actual words are followed by a hyphen, except when the first character following the hyphen would be something other than a letter, in which case the hyphen is omitted. Short, unpronounceable prefixes ("fx" and "fl") are not followed by a hyphen.

By convention, the names of condition types start with "&".

7. Библиотеки

Библиотеки являются частями программы, которые могут поставляться независимо. Система библиотек поддерживает макроопределения внутри библиотек, макроэкспорт, а также различает фазы, в которых необходимы определения и импорт. В данной главе описана нотация библиотек и семантика расширения и реализации библиотек.

7.1. Библиотечная форма

Определение библиотеки имеет следующую форму:

```
(library (library name)
   (export \( \text{export spec} \) ...)
   (import \(\delta\) import spec\(\text{\cdots}\) ...)
  (library body))
```

Объявление библиотеки содержит следующие элементы:

- (library name) указывает имя библиотеки (возможно с версией).
- Подформа **export** указывает список экспорта, именующий подмножество привязок, определённых внутри или импортированных в библиотеку.
- Подформа **import** указывает импортированные привязки в виде списка зависимостей импорта, где каждая зависимость указывает:
 - имя импортируемой библиотеки и, при необходимости, ограничения её версии,
 - релевантные уровни, например, время разворачивания или выполнения (см секцию 7.2, и

- подмножество библиотечных экспортов, чтобы сделать доступный внутри библиотеки импортирования, и локальных имён, для использования внутри библиотеки импортирования для каждого из экспортов библиотеки.
- (library body) тело библиотеки, состоящее из последовательности определений и следующей за ней последовательности выражений. Определения могут быть как для локальных (неэкспортируемых), так и для экспортируемых связываний, а выражения являются инициализирующими выражениями, которые будут вычисляться для их эффектов.

Идентификатор может импортироваться с тем же локальным именем из двух или более библиотек, или для двух уровней из той же библиотеки только в случае, если привязки, экспортируемые каждой библиотекой, тождественны (то есть, связывание определено в одной библиотеке, и оно поступает только через импорт, экспортируя и реэкспортируя). В противном случае идентификатор не может быть импортирован несколько раз, определён несколько раз, или определён и импортирован. Идентификаторы не видимы внутри библиотеки, за исключением явно импортированных в библиотеку или определённых внутри библиотеки.

(library name) однозначно идентифицирует библиотеку внутри реализации и является глобально видимым в разделах import (см. ниже) всех других библиотек внутри реализации. (library name) имеет следующую форму:

```
(\langle identifier_1 \rangle \langle identifier_2 \rangle ... \langle version \rangle)
```

где (version) является пустым или принимает следующую форму:

```
((sub-version) ...)
```

Каждый (sub-version) должен представлять точный неотрицательный целый объект. Пустой (version) эквивалентен ().

(export spec) именует совокупность импортированных и локально определённых привязок для экспортирования, возможно с другими внешними именами. (export spec) должен иметь одну из следующих форм:

```
(identifier)
(rename (\langle identifier_1 \rangle \langle identifier_2 \rangle) ...)
```

В (export spec), (identifier) именует одиночную привязку, определённую внутри или импортированную в библиотеку, причём внешнее имя экспорта совпадает с именем привязки внутри библиотеки. Спецификация rename экспортирует привязку с именем (identifier₁) в каждой паре ((identifier₁) $\langle identifier_2 \rangle$), используя $\langle identifier_2 \rangle$ в качестве внешнего имени.

Каждый (import spec) указывает множество привязок, импортируемых в библиотеку, уровни, на которых они должны быть доступны и локальные имена, которыми они должны быть названы. (import spec) должен быть одним из следуюшего:

```
(import set)
(for (import set) (import level) ...)
```

(import level) является одним из следующего:

```
expand
(meta (level))
```

Где (level) представляет точный целый объект.

Как (import level), run является сокращением для (meta 0), a expand - сокращением для (meta 1). Уровни и фазы описаны в секции 7.2.

(import set) именует множество привязок из другой библиотеки и, возможно, определяет локальные имена для импортированных привязок. Он должен быть одним из следующего:

```
(library reference)
(library \langle library reference \rangle)
(only (import set) (identifier) ...)
(except (import set) (identifier) ...)
(prefix ⟨import set⟩ ⟨identifier⟩)
(rename \langle import set \rangle (\langle identifier_1 \rangle \langle identifier_2 \rangle) ...)
```

(library reference) идентифицирует библиотеку её именем и, произвольно, её версией. Он имеет одну из следующих форм:

```
(\langle identifier_1 \rangle \langle identifier_2 \rangle ...)
(\langle identifier_1 \rangle \langle identifier_2 \rangle \dots \langle version reference \rangle)
```

(library reference), чьим первым (identifier) является for, library, only, except, prefix или rename, разрешается только внутри library (import set). (import set) (library reference)) в противном случае эквивалентен (library reference).

(library reference) без (version reference) (первая форма выше) эквивалентен (library reference) с (version reference) ().

(version reference) указывает множество (version), которым он соответствует. (library reference) идентифицирует все библиотеки того же самого имени и чья версия соответствует (version reference). (version reference) имеет следующую форму:

```
(\langle \text{sub-version reference}_1 \rangle ... \langle \text{sub-version reference}_n \rangle)
(and (version reference) ...)
(or (version reference) ...)
(not \( \text{version reference} \))
```

⟨version reference⟩ первой формы соответствует ⟨version⟩ с по крайней мере n элементы, $\langle \text{sub-version reference} \rangle$ которых соответствует соответств. (sub-version). and (version reference) соответствует версии, если (version references) после and соответствуют этому. Соответственно, **or** (version reference) соответствует версии, если один из (version references) после от соответствуют этому, и **not** ⟨version reference⟩ соответствует версии, если (version references) после этого не соответствует этому.

(sub-version reference) имеет одну из следующих форм:

```
(sub-version)
(>= \(\sub-version\))
(<= \(\langle\) sub-version\(\rangle\)
(and \(\sub-version\) reference \(\) ...)
(or \( \sub-version \) reference \( \) ...)
(not \( \sub-version reference \))
```

(sub-version reference) первой формы соответствует (sub-version), если они равны. >= (sub-version reference) первой формы соответствует sub-version, если оно больше или равно (sub-version) после него; аналогично для <=. and (sub-version reference) cootbetctbyet sub-version, если все последующие (sub-version reference) соответствуют ему. Соответственно, ог (sub-version reference) соответствует sub-version, если один из последующих (sub-version reference) соответствует ему, и not (sub-version reference) соответствует sub-version, если последующий (sub-version reference) не соответствует ему.

Примеры:

version reference		version	match?
()		(1)	yes
(1)		(1)	yes
(1)		(2)	no
(2 3)		(2)	no
(2 3)		(2 3)	yes
(2 3)		(2 3 5)	yes
(or (1 (>= 1))	(2))	(2)	yes
(or (1 (>= 1))	(2))	$(1 \ 1)$	yes
(or (1 (>= 1))	(2))	(1 0)	no
((or 1 2 3))		(1)	yes
((or 1 2 3))		(2)	yes
((or 1 2 3))		(3)	yes
((or 1 2 3))		(4)	no

Если при обращении к библиотеке идентифицировано более одной библиотеки, выбор библиотеки определяется неким зависимым от реализации методом.

Во избежании проблем, таких, как несовместимость типов и дублирование состояний, реализация должна запретить сосуществование в одной программе двух библиотек, библиотечные имена которых состоят из одинаковой последовательности идентификаторов, но версии которых являются несоответствующими.

По умолчанию все экспортируемые привязки из импортируемой библиотеки предполагаются видимыми внутри импортированной библиотеки с именами, присвоенными привязкам в импортируемой библиотеке. Точный набор импортитуемых привязок и имён этих привязок может быть установлен с помощью форм only, except, prefix и rename как описано ниже.

- Форма only порождает подмножество привязок из иного (import set), содержащее только перечисленные (identifier). Включенные (identifier) должны существовать в исходном (import set).
- An except form produces a subset of the bindings from another (import set), including all but the listed

(identifier)s. All of the excluded (identifier)s must be in the original (import set).

- A prefix form adds the (identifier) prefix to each name from another (import set).
- A rename form, (rename ($\langle identifier_1 \rangle \langle identifier_2 \rangle$) ...), removes the bindings for (identifier₁) ... to form an intermediate (import set), then adds the bindings back for the corresponding (identifier₂) ... to form the final (import set). Each (identifier₁) must be in the original (import set), each (identifier₂) must not be in the intermediate (import set), and the (identifier₂)s must be distinct.

It is a syntax violation if a constraint given above is not met.

The (library body) of a library form consists of forms that are classified as definitions or expressions. Which forms belong to which class depends on the imported libraries and the result of expansion—see chapter 10. Generally, forms that are not definitions (see section 11.2 for definitions available through the base library) are expressions.

A (library body) is like a (body) (see section 11.3) except that a (library body)s need not include any expressions. It must have the following form:

```
(definition) ... (expression) ...
```

When begin, let-syntax, or letrec-syntax forms occur in a top-level body prior to the first expression, they are spliced into the body; see section 11.4.7. Some or all of the body, including portions wrapped in begin, let-syntax, or letrec-syntax forms, may be specified by a syntactic abstraction (see section 9.2).

The transformer expressions and bindings are evaluated and created from left to right, as described in chapter 10. The expressions of variable definitions are evaluated from left to right, as if in an implicit letrec*, and the body expressions are also evaluated from left to right after the expressions of the variable definitions. A fresh location is created for each exported variable and initialized to the value of its local counterpart. The effect of returning twice to the continuation of the last body expression is unspecified.

Note: The names library, export, import, for, run, expand, meta, import, export, only, except, prefix, rename, and, or, not, >=, and <= appearing in the library syntax are part of the syntax and are not reserved, i.e., the same names can be used for other purposes within the library or even exported from or imported into a library with different meanings, without affecting their use in the library form.

Bindings defined with a library are not visible in code outside of the library, unless the bindings are explicitly exported from the library. An exported macro may, however, implicitly export an otherwise unexported identifier defined within or imported into the library. That is, it may insert a reference to that identifier into the output code it produces.

All explicitly exported variables are immutable in both the exporting and importing libraries. It is thus a syntax violation if an explicitly exported variable appears on the left-hand side of a set! expression, either in the exporting or importing libraries.

All implicitly exported variables are also immutable in both the exporting and importing libraries. It is thus a syntax violation if a variable appears on the left-hand side of a set! expression in any code produced by an exported macro outside of the library in which the variable is defined. It is also a syntax violation if a reference to an assigned variable appears in any code produced by an exported macro outside of the library in which the variable is defined, where an assigned variable is one that appears on the left-hand side of a set! expression in the exporting library.

All other variables defined within a library are mutable.

7.2. Import and export levels

Expanding a library may require run-time information from another library. For example, if a macro transformer calls a procedure from library A, then the library A must be instantiated before expanding any use of the macro in library B. Library A may not be needed when library B is eventually run as part of a program, or it may be needed for run time of library B, too. The library mechanism distinguishes these times by phases, which are explained in this section.

Every library can be characterized by expand-time information (minimally, its imported libraries, a list of the exported keywords, a list of the exported variables, and code to evaluate the transformer expressions) and run-time information (minimally, code to evaluate the variable definition right-handside expressions, and code to evaluate the body expressions). The expand-time information must be available to expand references to any exported binding, and the run-time information must be available to evaluate references to any exported variable binding.

A phase is a time at which the expressions within a library are evaluated. Within a library body, top-level expressions and the right-hand sides of define forms are evaluated at run time, i.e., phase 0, and the right-hand sides of define-syntax forms are evaluated at expand time, i.e., phase 1. When definesyntax, let-syntax, or letrec-syntax forms appear within code evaluated at phase n, the right-hand sides are evaluated at phase n+1.

These phases are relative to the phase in which the library itself is used. An instance of a library corresponds to an evaluation of its variable definitions and expressions in a particular phase relative to another library—a process called instantiation. For example, if a top-level expression in a library B refers to a variable export from another library A, then it refers to the export from an instance of A at phase 0 (relative to the phase of B). But if a phase 1 expression within B refers to the same binding from A, then it refers to the export from an instance of A at phase 1 (relative to the phase of B).

A visit of a library corresponds to the evaluation of its syntax definitions in a particular phase relative to another library—a process called *visiting*. For example, if a top-level expression in a library B refers to a macro export from another library A, then it refers to the export from a visit of A at phase 0 (relative to the phase of B), which corresponds to the evaluation of the macro's transformer expression at phase 1.

A *level* is a lexical property of an identifier that determines in which phases it can be referenced. The level for each identifier bound by a definition within a library is 0; that is, the identifier can be referenced only at phase 0 within the library. The level for each imported binding is determined by the enclosing for form of the import in the importing library, in addition to the levels of the identifier in the exporting library. Import and export levels are combined by pairwise addition of all level combinations. For example, references to an imported identifier exported for levels p_a and p_b and imported for levels q_a , q_b , and q_c are valid at levels $p_a + q_a$, $p_a + q_b$, $p_a + q_c$, $p_b + q_a$, $p_b + q_b$, and $p_b + q_c$. An (import set) without an enclosing for is equivalent to (for (import set) run), which is the same as (for (import set) (meta 0)).

The export level of an exported binding is 0 for all bindings that are defined within the exporting library. The export levels of a reexported binding, i.e., an export imported from another library, are the same as the effective import levels of that binding within the reexporting library.

For the libraries defined in the library report, the export level is 0 for nearly all bindings. The exceptions are syntax-rules, identifier-syntax, ..., and from the (rnrs base (6) library, which are exported with level 1, set! from the (rnrs base (6)) library, which is exported with levels 0 and 1, and all bindings from the composite (rnrs (6)) library (see library chapter ??), which are exported with levels 0 and 1.

Macro expansion within a library can introduce a reference to an identifier that is not explicitly imported into the library. In that case, the phase of the reference must match the identifier's level as shifted by the difference between the phase of the source library (i.e., the library that supplied the identifier's lexical context) and the library that encloses the reference. For example, suppose that expanding a library invokes a macro transformer, and the evaluation of the macro transformer refers to an identifier that is exported from another library (so the phase-1 instance of the library is used); suppose further that the value of the binding is a syntax object representing an identifier with only a level-nbinding; then, the identifier must be used only at phase n+1in the library being expanded. This combination of levels and phases is why negative levels on identifiers can be useful, even though libraries exist only at non-negative phases.

If any of a library's definitions are referenced at phase 0 in the expanded form of a program, then an instance of the referenced library is created for phase 0 before the program's definitions and expressions are evaluated. This rule applies transitively: if the expanded form of one library references at phase 0 an identifier from another library, then before the referencing library is instantiated at phase n, the referenced library must be instantiated at phase n. When an identifier is referenced at any phase n greater than 0, in contrast, then the defining library is instantiated at phase n at some unspecified time before the

reference is evaluated. Similarly, when a macro keyword is referenced at phase n during the expansion of a library, then the defining library is visited at phase n at some unspecified time before the reference is evaluated.

An implementation may distinguish instances/visits of a library for different phases or to use an instance/visit at any phase as an instance/visit at any other phase. An implementation may further expand each library form with distinct visits of libraries in any phase and/or instances of libraries in phases above 0. An implementation may create instances/visits of more libraries at more phases than required to satisfy references. When an identifier appears as an expression in a phase that is inconsistent with the identifier's level, then an implementation may raise an exception either at expand time or run time, or it may allow the reference. Thus, a library whose meaning depends on whether the instances of a library are distinguished or shared across phases or library expansions may be unportable.

7.3. Examples

Examples for various (import spec)s and (export spec)s:

```
(library (stack)
 (export make push! pop! empty!)
 (import (rnrs))
 (define (make) (list '()))
 (define (push! s v) (set-car! s (cons v (car s)\binom{l}{r} prary (my-helpers values-stuff)
 (define (pop! s) (let ([v (caar s)])
                  (set-car! s (cdar s))
                  v))
 (define (empty! s) (set-car! s '())))
(library (balloons)
 (export make push pop)
 (import (rnrs))
 (define (make w h) (cons w h))
 (define (push b amt)
   (cons (- (car b) amt) (+ (cdr b) amt)))
 (define (pop b) (display "Boom! ")
                (display (* (car b) (cdr b)))
                (newline)))
(library (party)
 ;; Total exports:
 ;; make, push, push!, make-party, pop!
 (export (rename (balloon:make make)
               (balloon:push push))
        push!
        make-party
        (rename (party-pop! pop!)))
 (import (rnrs)
        (only (stack) make push! pop!) ; not empty!
        (prefix (balloons) balloon:))
 ;; Creates a party as a stack of balloons,
 ;; starting with two balloons
 (define (make-party)
   (let ([s (make)]) ; from stack
```

```
(push! s (balloon:make 10 10))
     (push! s (balloon:make 12 9))
    s))
 (define (party-pop! p)
   (balloon:pop (pop! p))))
(library (main)
 (export)
 (import (rnrs) (party))
 (define p (make-party))
 (pop! p) ; displays "Boom! 108"
 (push! p (push (make 5 5) 1))
 (pop! p))
                ; displays "Boom! 24"
```

Examples for macros and phases:

(export find-dup) (import (rnrs))

(library (my-helpers id-stuff)

```
(define (find-dup 1)
   (and (pair? 1)
       (let loop ((rest (cdr l)))
         (cond
          [(null? rest) (find-dup (cdr l))]
          [(bound-identifier=? (car 1) (car rest))
           (car rest)]
          [else (loop (cdr rest))])))))
  (export mvlet)
 (import (rnrs) (for (my-helpers id-stuff) expand))
 (define-syntax mvlet
   (lambda (stx)
     (syntax-case stx ()
      [( [(id ...) expr] body0 body ...)
       (not (find-dup (syntax (id ...))))
       (syntax
         (call-with-values
             (lambda () expr)
           (lambda (id ...) body0 body ...)))]))))
(library (let-div)
 (export let-div)
 (import (rnrs)
        (my-helpers values-stuff)
        (rnrs r5rs))
 (define (quotient+remainder n d)
   (let ([q (quotient n d)])
     (values q (- n (* q d)))))
 (define-syntax let-div
   (syntax-rules ()
    [( n d (q r) body0 body ...)
     (mvlet [(q r) (quotient+remainder n d)]
      body0 body ...)])))
```

Top-level programs

A top-level program specifies an entry point for defining and running a Scheme program. A top-level program specifies a set

of libraries to import and code to run. Through the imported libraries, whether directly or through the transitive closure of importing, a top-level program defines a complete Scheme program.

8.1. Top-level program syntax

A top-level program is a delimited piece of text, typically a file, that has the following form:

```
(import form) (top-level body)
```

An (import form) has the following form:

```
(import ⟨import spec⟩ ...)
```

A (top-level body) has the following form:

```
⟨top-level body form⟩ ...
```

A \langle top-level body form \rangle is either a \langle definition \rangle or an (expression).

The (import form) is identical to the import clause in libraries (see section 7.1), and specifies a set of libraries to import. A ⟨top-level body⟩ is like a ⟨library body⟩ (see section 7.1), except that definitions and expressions may occur in any order. Thus, the syntax specified by (top-level body form) refers to the result of macro expansion.

When uses of begin, let-syntax, or letrec-syntax from the (rnrs base (6)) library occur in a top-level body prior to the first expression, they are spliced into the body; see section 11.4.7. Some or all of the body, including portions wrapped in begin, let-syntax, or letrecsyntax forms, may be specified by a syntactic abstraction (see section 9.2).

8.2. Top-level program semantics

A top-level program is executed by treating the program similarly to a library, and evaluating its definitions and expressions. The semantics of a top-level body may be roughly explained by a simple translation into a library body: Each (expression) that appears before a definition in the top-level body is converted into a dummy definition

```
(define (variable) (begin (expression) (unspecified)))
```

where (variable) is a fresh identifier and (unspecified) is a side-effect-free expression returning an unspecified value. (It is generally impossible to determine which forms are definitions and expressions without concurrently expanding the body, so the actual translation is somewhat more complicated; see chapter 10.)

On platforms that support it, a top-level program may access its command line by calling the command-line procedure (see library section ??).

9. **Primitive syntax**

After the import form within a library form or a toplevel program, the forms that constitute the body of the library or the top-level program depend on the libraries that are imported. In particular, imported syntactic keywords determine the available syntactic abstractions and whether each form is a definition or expression. A few form types are always available independent of imported libraries, however, including constant literals, variable references, procedure calls, and macro uses.

9.1. Primitive expression types

The entries in this section all describe expressions, which may occur in the place of (expression) syntactic variables. See also section 11.4.

Constant literals

```
(number)
                                                          syntax
(boolean)
                                                          syntax
(character)
                                                          syntax
⟨string⟩
                                                          syntax
(bytevector)
                                                          svntax
```

An expression consisting of a representation of a number object, a boolean, a character, a string, or a bytevector, evaluates "to itself".

```
145932
                            145932
#t
                            #t
"abc"
                         ⇒ "abc"
#vu8(2 24 123)
                         \implies #vu8(2 24 123)
```

As noted in section 5.10, the value of a literal expression is immutable.

Variable references

(variable) syntax

An expression consisting of a variable (section 5.2) is a variable reference if it is not a macro use (see below). The value of the variable reference is the value stored in the location to which the variable is bound. It is a syntax violation to reference an unbound variable.

The following example examples assumes the base library has been imported:

```
(define x 28)
                              28
```

Procedure calls

```
(\langle operator \rangle \langle operand_1 \rangle \dots)
```

A procedure call consists of expressions for the procedure to be called and the arguments to be passed to it, with enclosing parentheses. A form in an expression context is a procedure call if (operator) is not an identifier bound as a syntactic keyword (see section 9.2 below).

When a procedure call is evaluated, the operator and operand expressions are evaluated (in an unspecified order) and the resulting procedure is passed the resulting arguments.

The following examples assume the (rnrs base (6)) library has been imported:

```
(+34)
12
```

If the value of (operator) is not a procedure, an exception with condition type &assertion is raised. Also, if (operator) does not accept as many arguments as there are (operand)s, an exception with condition type &assertion is raised.

Note: In contrast to other dialects of Lisp, the order of evaluation is unspecified, and the operator expression and the operand expressions are always evaluated with the same evaluation rules.

Although the order of evaluation is otherwise unspecified, the effect of any concurrent evaluation of the operator and operand expressions is constrained to be consistent with some sequential order of evaluation. The order of evaluation may be chosen differently for each procedure call.

Note: In many dialects of Lisp, the form () is a legitimate expression. In Scheme, expressions written as list/pair forms must have at least one subexpression, so () is not a syntactically valid expression.

9.2. Macros

Libraries and top-level programs can define and use new kinds of derived expressions and definitions called syntactic abstractions or macros. A syntactic abstraction is created by binding a keyword to a macro transformer or, simply, transformer. The transformer determines how a use of the macro (called a *macro* use) is transcribed into a more primitive form.

Most macro uses have the form:

```
(\langle keyword \rangle \langle datum \rangle \ldots \rangle \rangle
```

where (keyword) is an identifier that uniquely determines the kind of form. This identifier is called the *syntactic keyword*, or simply *keyword*, of the macro. The number of (datum)s and the syntax of each depends on the syntactic abstraction.

Macro uses can also take the form of improper lists, singleton identifiers, or set! forms, where the second subform of the set! is the keyword (see section 11.19) library section ??):

```
(\langle keyword \rangle \langle datum \rangle \ldots \langle datum \rangle \ldots \langle datum \rangle \rangle \ldots \langle datum \rangle \rangle \ldots \ldots
(keyword)
(set! (keyword) (datum))
```

The define-syntax, let-syntax and letrecsyntax forms, described in sections 11.2.2 and 11.18, create bindings for keywords, associate them with macro transformers, and control the scope within which they are visible.

The syntax-rules and identifier-syntax forms. described in section 11.19, create transformers via a pattern language. Moreover, the syntax-case form, described in library chapter ??, allows creating transformers via arbitrary Scheme code.

Keywords occupy the same name space as variables. That is, within the same scope, an identifier can be bound as a variable or keyword, or neither, but not both, and local bindings of either kind may shadow other bindings of either kind.

Macros defined using syntax-rules and identifiersyntax are "hygienic" and "referentially transparent" and thus preserve Scheme's lexical scoping [?, ?, ?, ?, ?]:

- If a macro transformer inserts a binding for an identifier (variable or keyword) not appearing in the macro use, the identifier is in effect renamed throughout its scope to avoid conflicts with other identifiers.
- If a macro transformer inserts a free reference to an identifier, the reference refers to the binding that was visible where the transformer was specified, regardless of any local bindings that may surround the use of the macro.

Macros defined using the syntax-case facility are also hygienic unless datum->syntax (see library section ??) is used.

10. **Expansion process**

Macro uses (see section 9.2) are expanded into core forms at the start of evaluation (before compilation or interpretation) by a syntax expander. The set of core forms is implementationdependent, as is the representation of these forms in the expander's output. If the expander encounters a syntactic abstraction, it invokes the associated transformer to expand the syntactic abstraction, then repeats the expansion process for the form returned by the transformer. If the expander encounters a core form, it recursively processes its subforms that are in expression or definition context, if any, and reconstructs the form from the expanded subforms. Information about identifier bindings is maintained during expansion to enforce lexical scoping for variables and keywords.

To handle definitions, the expander processes the initial forms in a $\langle body \rangle$ (see section 11.3) or $\langle library body \rangle$ (see section 7.1) from left to right. How the expander processes each form encountered depends upon the kind of form.

macro use The expander invokes the associated transformer to transform the macro use, then recursively performs whichever of these actions are appropriate for the resulting

define-syntax form The expander expands and evaluates the right-hand-side expression and binds the keyword to the resulting transformer.

define form The expander records the fact that the defined identifier is a variable but defers expansion of the righthand-side expression until after all of the definitions have been processed.

begin form The expander splices the subforms into the list of body forms it is processing. (See section 11.4.7.)

let-syntax or letrec-syntax form The expander
splices the inner body forms into the list of (outer) body
forms it is processing, arranging for the keywords bound
by the let-syntax and letrec-syntax to be visible
only in the inner body forms.

expression, i.e., nondefinition The expander completes the expansion of the deferred right-hand-side expressions and the current and remaining expressions in the body, and then creates the equivalent of a letrec* form from the defined variables, expanded right-hand-side expressions, and expanded body expressions.

For the right-hand side of the definition of a variable, expansion is deferred until after all of the definitions have been seen. Consequently, each keyword and variable reference within the right-hand side resolves to the local binding, if any.

A definition in the sequence of forms must not define any identifier whose binding is used to determine the meaning of the undeferred portions of the definition or any definition that precedes it in the sequence of forms. For example, the bodies of the following expressions violate this restriction.

The following do not violate the restriction.

```
(let ([x 5])
 (define lambda list)
 (lambda x x))
                           (55)
(let-syntax ([def0 (syntax-rules ()
                  [(_ x) (define x 0)])])
 (let ([z 3])
   (define def0 list)
   (def0 z)
   (list z)))
                            (3)
(let ()
 (define-syntax foo
   (lambda (e)
     (let ([+-]) (+ 1 2)))
 (define + 2)
                        (foo))
```

The implementation should treat a violation of the restriction as a syntax violation.

Note that this algorithm does not directly reprocess any form. It requires a single left-to-right pass over the definitions followed by a single pass (in any order) over the body expressions and deferred right-hand sides.

Example:

```
(lambda (x)
  (define-syntax defun
        (syntax-rules ()
        [(_ x a e) (define x (lambda a e))]))
  (defun even? (n) (or (= n 0) (odd? (- n 1))))
  (define-syntax odd?
        (syntax-rules () [(_ n) (not (even? n))]))
  (odd? (if (odd? x) (* x x) x)))
```

In the example, the definition of defun is encountered first, and the keyword defun is associated with the transformer resulting from the expansion and evaluation of the corresponding righthand side. A use of defun is encountered next and expands into a define form. Expansion of the right-hand side of this define form is deferred. The definition of odd? is next and results in the association of the keyword odd? with the transformer resulting from expanding and evaluating the corresponding right-hand side. A use of odd? appears next and is expanded; the resulting call to not is recognized as an expression because not is bound as a variable. At this point, the expander completes the expansion of the current expression (the call to not) and the deferred right-hand side of the even? definition; the uses of odd? appearing in these expressions are expanded using the transformer associated with the keyword odd?. The final output is the equivalent of

although the structure of the output is implementation-dependent.

Because definitions and expressions can be interleaved in a (top-level body) (see chapter 8), the expander's processing of a (top-level body) is somewhat more complicated. It behaves as described above for a \langle body \rangle or \langle library body \rangle with the following exceptions: When the expander finds a nondefinition, it defers its expansion and continues scanning for definitions. Once it reaches the end of the set of forms, it processes the deferred right-hand-side and body expressions, then generates the equivalent of a letrec* form from the defined variables, expanded right-hand-side expressions, and expanded body expressions. For each body expression (expression) that appears before a variable definition in the body, a dummy binding is created at the corresponding place within the set of letrec* bindings, with a fresh temporary variable on the left-hand side and the equivalent of (begin (expression) (unspecified)), where (unspecified) is a side-effect-free expression returning an unspecified value, on the right-hand side, so that left-toright evaluation order is preserved. The begin wrapper allows (expression) to evaluate to an arbitrary number of values.

11. **Base library**

This chapter describes Scheme's (rnrs base (6)) library, which exports many of the procedure and syntax bindings that are traditionally associated with Scheme.

Section 11.20 defines the rules that identify tail calls and tail contexts in constructs from the (rnrs base (6)) library.

11.1. Base types

No object satisfies more than one of the following predicates:

```
boolean?
                 pair?
symbol?
                number?
char?
                string?
                procedure?
vector?
null?
```

These predicates define the base types boolean, pair, symbol, number, char (or character), string, vector, and procedure. Moreover, the empty list is a special object of its own type.

Note that, although there is a separate boolean type, any Scheme value can be used as a boolean value for the purpose of a conditional test; see section 5.7.

11.2. Definitions

Definitions may appear within a \(\text{top-level body}\)\(\text{ (section 8.1)}, at the top of a (library body) (section 7.1), or at the top of a ⟨body⟩ (section 11.3).

A (definition) may be a variable definition (section 11.2.1) or keyword definition (section 11.2.1). Macro uses that expand into definitions or groups of definitions (packaged in a begin, let-syntax, or letrec-syntax form; see section 11.4.7) may also appear wherever other definitions may appear.

11.2.1. Variable definitions

The define form described in this section is a (definition) used to create variable bindings and may appear anywhere other definitions may appear.

```
(define ⟨variable⟩ ⟨expression⟩)
                                                               syntax
(define (variable))
                                                               syntax
(define ((variable) (formals)) (body))
                                                               syntax
(define (\langle variable \rangle . \langle formal \rangle) \langle body \rangle)
                                                               syntax
```

The first from of define binds (variable) to a new location before assigning the value of (expression) to it.

```
(define add3
 (lambda (x) (+ x 3)))
(add3 3)
(define first car)
(first '(1 2))
```

The continuation of (expression) should not be invoked more than once.

Implementation responsibilities: Implementations should detect that the continuation of (expression) is invoked more than once. If the implementation detects this, it must raise an exception with condition type &assertion.

The second form of define is equivalent to

```
(define (variable) (unspecified))
```

where (unspecified) is a side-effect-free expression returning an unspecified value.

In the third form of define, (formals) must be either a sequence of zero or more variables, or a sequence of one or more variables followed by a dot . and another variable (as in a lambda expression, see section 11.4.2). This form is equivalent

```
(define (variable)
   (lambda (\langle formals \rangle) \langle body \rangle)).
```

In the fourth form of define, (formal) must be a single variable. This form is equivalent to

```
(define (variable)
   (lambda \langle formal \rangle \langle body \rangle)).
```

11.2.2. Syntax definitions

The define-syntax form described in this section is a (definition) used to create keyword bindings and may appear anywhere other definitions may appear.

```
(define-syntax \( \langle keyword \rangle \( \langle expression \rangle \right) \)
                                                                                             syntax
```

Binds (keyword) to the value of (expression), which must evaluate, at macro-expansion time, to a transformer. Macro transformers can be created using the syntax-rules and identifier-syntax forms described in section 11.19. See library section ?? for a more complete description of transformers.

Keyword bindings established by define-syntax are visible throughout the body in which they appear, except where shadowed by other bindings, and nowhere else, just like variable bindings established by define. All bindings established by a set of definitions, whether keyword or variable definitions, are visible within the definitions themselves.

Implementation responsibilities: The implementation should detect if the value of (expression) cannot possibly be a transformer.

Example:

An implication of the left-to-right processing order (section 10) is that one definition can affect whether a subsequent form is also a definition.

Example:

The behavior is unaffected by any binding for bind-to-zero that might appear outside of the let expression.

11.3. Bodies

The $\langle body \rangle$ of a lambda, let, let*, let-values, let*-values, letrec, or letrec* expression, or that of a definition with a body consists of zero or more definitions followed by one or more expressions.

```
\langle definition \rangle ... \langle expression_1 \rangle \langle expression_2 \rangle ...
```

Each identifier defined by a definition is local to the $\langle body \rangle$. That is, the identifier is bound, and the region of the binding is the entire $\langle body \rangle$ (see section 5.2).

Example:

```
(let ((x 5))

(define foo (lambda (y) (bar x y)))

(define bar (lambda (a b) (+ (* a b) a)))

(foo (+ x 3))) \Longrightarrow 45
```

When begin, let-syntax, or letrec-syntax forms occur in a body prior to the first expression, they are spliced into the body; see section 11.4.7. Some or all of the body, including portions wrapped in begin, let-syntax, or letrec-syntax forms, may be specified by a macro use (see section 9.2).

An expanded \(\begin{aligned} \delta body \rangle \) (see chapter 10) containing variable definitions can always be converted into an equivalent letrec* expression. For example, the let expression in the above example is equivalent to

11.4. Expressions

The entries in this section describe the expressions of the (rnrs base (6)) library, which may occur in the position of the (expression) syntactic variable in addition to the primitive expression types as described in section 9.1.

11.4.1. Quotation

```
(quote \langle datum \rangle) syntax
```

Syntax: (Datum) should be a syntactic datum.

Semantics: (quote (datum)) evaluates to the datum value represented by (datum) (see section 4.3). This notation is used to include constants.

```
 (\text{quote a}) \qquad \Longrightarrow \qquad \text{a} 
 (\text{quote #(a b c)}) \qquad \Longrightarrow \qquad \text{#(a b c)} 
 (\text{quote (+ 1 2)}) \qquad \Longrightarrow \qquad \text{(+ 1 2)}
```

As noted in section 4.3.5, (quote $\langle datum \rangle$) may be abbreviated as ' $\langle datum \rangle$:

```
'"abc" ⇒ "abc"
'145932 ⇒ 145932
'a ⇒ a
'#(a b c) ⇒ #(a b c)
'() ⇒ ()
'(+12) ⇒ (+12)
'(quote a) ⇒ (quote a)
"a ⇒ (quote a)
```

As noted in section 5.10, constants are immutable.

Note: Different constants that are the value of a quote expression may share the same locations.

11.4.2. Procedures

```
(lambda \langle formals \rangle \langle body \rangle) syntax
```

Syntax: $\langle Formals \rangle$ must be a formal parameter list as described below, and $\langle body \rangle$ must be as described in section 11.3.

Semantics: A lambda expression evaluates to a procedure. The environment in effect when the lambda expression is evaluated is remembered as part of the procedure. When the procedure is later called with some arguments, the environment in which the lambda expression was evaluated is extended by binding the variables in the parameter list to fresh locations, and the resulting argument values are stored in those locations. Then, the expressions in the body of the lambda expression (which may contain definitions and thus represent a letrec* form, see section 11.3) are evaluated sequentially in the extended environment. The results of the last expression in the body are returned as the results of the procedure call.

```
\begin{array}{lll} \text{(lambda (x) (+ x x))} & \Longrightarrow & a \ procedure \\ \text{((lambda (x) (+ x x)) 4)} & \Longrightarrow & 8 \\ \\ \text{((lambda (x))} & \end{array}
```

```
(define (p y)
    (+ y 1))
  (+ (p x) x))
                          \implies 11
(define reverse-subtract
 (lambda (x y) (-y x)))
(reverse-subtract 7 10) \implies 3
(define add4
 (let ((x 4))
   (lambda (y) (+ x y)))
(add4 6)
```

(Formals) must have one of the following forms:

- $(\langle \text{variable}_1 \rangle \dots)$: The procedure takes a fixed number of arguments; when the procedure is called, the arguments are stored in the bindings of the corresponding variables.
- (variable): The procedure takes any number of arguments; when the procedure is called, the sequence of arguments is converted into a newly allocated list, and the list is stored in the binding of the (variable).
- $(\langle \text{variable}_1 \rangle \dots \langle \text{variable}_n \rangle \cdot \langle \text{variable}_{n+1} \rangle)$: If a period . precedes the last variable, then the procedure takes nor more arguments, where n is the number of parameters before the period (there must be at least one). The value stored in the binding of the last variable is a newly allocated list of the arguments left over after all the other arguments have been matched up against the other parameters.

```
((lambda x x) 3 4 5 6)
                            \implies (3 4 5 6)
((lambda (x y . z) z)
3 4 5 6)
                            \implies (5 6)
```

Any (variable) must not appear more than once in (formals).

11.4.3. Conditionals

```
(if \langle test \rangle \langle consequent \rangle \langle alternate \rangle)
                                                                                                       syntax
(if \langle test \rangle \langle consequent \rangle)
                                                                                                       syntax
```

Syntax: (Test), (consequent), and (alternate) must be expressions.

Semantics: An if expression is evaluated as follows: first, \(\text{test} \) is evaluated. If it yields a true value (see section 5.7), then (consequent) is evaluated and its values are returned. Otherwise (alternate) is evaluated and its values are returned. If (test) yields #f and no (alternate) is specified, then the result of the expression is unspecified.

```
(if (> 3 2) 'yes 'no)
                              yes
(if (> 2 3) 'yes 'no)
                              nο
(if (> 3 2)
   (-32)
   (+32)
                          \implies 1
                         ⇒ unspecified
(if #f #f)
```

The (consequent) and (alternate) expressions are in tail context if the if expression itself is; see section 11.20.

11.4.4. Assignments

```
(set! ⟨variable⟩ ⟨expression⟩)
                                                    syntax
```

(Expression) is evaluated, and the resulting value is stored in the location to which (variable) is bound. (Variable) must be bound either in some region enclosing the set! expression or at the top level. The result of the set! expression is unspecified.

```
(let ((x 2))
  (+ \times 1)
  (set! x 4)
  (+ \times 1)
```

It is a syntax violation if (variable) refers to an immutable binding.

Note: The identifier set! is exported with level 1 as well. See section 11.19.

11.4.5. Derived conditionals

```
(cond \ \langle cond \ clause_1 \rangle \ \langle cond \ clause_2 \rangle \dots)
                                                                             syntax
                                                                auxiliary syntax
                                                                auxiliary syntax
else
```

Syntax: Each (cond clause) must be of the form

```
(\langle \text{test} \rangle \langle \text{expression}_1 \rangle \dots)
```

where $\langle \text{test} \rangle$ is an expression. Alternatively, a $\langle \text{cond clause} \rangle$ may be of the form

```
(\langle \text{test} \rangle => \langle \text{expression} \rangle)
```

The last (cond clause) may be an "else clause", which has the form

```
(else \langle expression_1 \rangle \langle expression_2 \rangle \dots ).
```

Semantics: A cond expression is evaluated by evaluating the (test) expressions of successive (cond clause)s in order until one of them evaluates to a true value (see section 5.7). When a \(\text{test} \) evaluates to a true value, then the remaining (expression)s in its (cond clause) are evaluated in order, and the results of the last (expression) in the (cond clause) are returned as the results of the entire cond expression. If the selected (cond clause) contains only the (test) and no (expression)s, then the value of the \langle test \rangle is returned as the result. If the selected \langle cond clause \rangle uses the => alternate form, then the (expression) is evaluated. Its value must be a procedure. This procedure should accept one argument; it is called on the value of the \(\text{test}\) and the values returned by this procedure are returned by the cond expression. If all \(\text{test}\)s evaluate to \(\pm\)f, and there is no else clause, then the conditional expression returns unspecified values; if there is an else clause, then its (expression)s are evaluated, and the values of the last one are returned.

```
(cond ((> 3 2) 'greater)
     ((< 3 2) 'less))
                          ⇒ greater
(cond ((> 3 3) 'greater)
     ((< 3 3) 'less)
     (else 'equal))
                               equal
(cond ('(1 2 3) => cadr)
     (else #f))
                          \Longrightarrow
```

For a (cond clause) of one of the following forms

```
(\langle test \rangle \langle expression_1 \rangle \dots)

(else \langle expression_1 \rangle \langle expression_2 \rangle \dots)
```

the last $\langle expression \rangle$ is in tail context if the cond form itself is. For a $\langle cond \ clause \rangle$ of the form

```
(\langle test \rangle => \langle expression \rangle)
```

the (implied) call to the procedure that results from the evaluation of $\langle expression \rangle$ is in a tail context if the cond form itself is. See section 11.20.

A sample definition of cond in terms of simpler forms is in appendix B.

```
(case \langle key \rangle \langle case\ clause_1 \rangle \langle case\ clause_2 \rangle ...) syntax Syntax: \langle Key \rangle must be an expression. Each \langle case\ clause \rangle must have one of the following forms:
```

```
((\langle datum_1 \rangle \dots) \langle expression_1 \rangle \langle expression_2 \rangle \dots)

(else \langle expression_1 \rangle \langle expression_2 \rangle \dots)
```

The second form, which specifies an "else clause", may only appear as the last $\langle case\ clause \rangle$. Each $\langle datum \rangle$ is an external representation of some object. The data represented by the $\langle datum \rangle$ s need not be distinct.

Semantics: A case expression is evaluated as follows. $\langle Key \rangle$ is evaluated and its result is compared using eqv? (see section 11.5) against the data represented by the $\langle datum \rangle$ s of each $\langle case\ clause \rangle$ in turn, proceeding in order from left to right through the set of clauses. If the result of evaluating $\langle key \rangle$ is equivalent to a datum of a $\langle case\ clause \rangle$, the corresponding $\langle expression \rangle$ s are evaluated from left to right and the results of the last expression in the $\langle case\ clause \rangle$ are returned as the results of the case expression. Otherwise, the comparison process continues. If the result of evaluating $\langle key \rangle$ is different from every datum in each set, then if there is an else clause its expressions are evaluated and the results of the last are the results of the case expression; otherwise the case expression returns unspecified values.

The last $\langle expression \rangle$ of a $\langle case\ clause \rangle$ is in tail context if the case expression itself is; see section 11.20.

```
(and \langle test_1 \rangle \dots) syntax
```

Syntax: The $\langle \text{test} \rangle$ s must be expressions.

Semantics: If there are no $\langle \text{test} \rangle$ s, #t is returned. Otherwise, the $\langle \text{test} \rangle$ expressions are evaluated from left to right until a $\langle \text{test} \rangle$ returns #f or the last $\langle \text{test} \rangle$ is reached. In the former case, the

and expression returns #f without evaluating the remaining expressions. In the latter case, the last expression is evaluated and its values are returned.

The and keyword could be defined in terms of if using syntax-rules (see section 11.19) as follows:

```
(define-syntax and
  (syntax-rules ()
      ((and) #t)
      ((and test) test)
      ((and test1 test2 ...)
      (if test1 (and test2 ...) #f))))
```

The last $\langle \text{test} \rangle$ expression is in tail context if the and expression itself is; see section 11.20.

```
(\text{or } \langle test_1 \rangle \dots) syntax
```

Syntax: The $\langle \text{test} \rangle$ s must be expressions.

Semantics: If there are no $\langle \text{test} \rangle$ s, #f is returned. Otherwise, the $\langle \text{test} \rangle$ expressions are evaluated from left to right until a $\langle \text{test} \rangle$ returns a true value val (see section 5.7) or the last $\langle \text{test} \rangle$ is reached. In the former case, the or expression returns val without evaluating the remaining expressions. In the latter case, the last expression is evaluated and its values are returned.

```
(or (= 2 2) (> 2 1)) \implies #t

(or (= 2 2) (< 2 1)) \implies #t

(or #f #f #f) \implies #f

(or '(b c) (/ 3 0)) \implies (b c)
```

The or keyword could be defined in terms of if using syntax-rules (see section 11.19) as follows:

```
(define-syntax or
  (syntax-rules ()
     ((or) #f)
     ((or test) test)
     ((or test1 test2 ...)
     (let ((x test1))
        (if x x (or test2 ...))))))
```

The last $\langle \text{test} \rangle$ expression is in tail context if the or expression itself is; see section 11.20.

11.4.6. Binding constructs

The binding constructs described in this section create local bindings for variables that are visible only in a delimited region. The syntax of the constructs let, let*, letrec, and letrec* is identical, but they differ in the regions (see section 5.2) they establish for their variable bindings and in the order in which the values for the bindings are computed. In a let expression, the initial values are computed before any of the variables become bound; in a let* expression, the bindings and evaluations are performed sequentially. In a letrec or

letrec* expression, all the bindings are in effect while their initial values are being computed, thus allowing mutually recursive definitions. In a letrec expression, the initial values are computed before being assigned to the variables; in a letrec*, the evaluations and assignments are performed sequentially.

In addition, the binding constructs let-values and let*values generalize let and let* to allow multiple variables to be bound to the results of expressions that evaluate to multiple values. They are analogous to let and let* in the way they establish regions: in a let-values expression, the initial values are computed before any of the variables become bound; in a let*-values expression, the bindings are performed sequentially.

Sample definitions of all the binding forms of this section in terms of simpler forms are in appendix B.

```
(let \langle bindings \rangle \langle body \rangle)
                                                                                         syntax
Syntax: (Bindings) must have the form
       ((\langle variable_1 \rangle \langle init_1 \rangle) \dots),
```

where each (init) is an expression, and (body) is as described in section 11.3. Any variable must not appear more than once in the (variable)s.

Semantics: The (init)s are evaluated in the current environment (in some unspecified order), the (variable)s are bound to fresh locations holding the results, the (body) is evaluated in the extended environment, and the values of the last expression of (body) are returned. Each binding of a (variable) has (body) as its region.

```
(let ((x 2) (y 3))
 (* x y))
                               6
(let ((x 2) (y 3))
 (let ((x 7)
      (z (+ x y)))
   (* z x)))
                               3.5
```

See also named let, section 11.16.

```
(let* \langle bindings \rangle \langle body \rangle)
                                                                                        syntax
Syntax: (Bindings) must have the form
       ((\langle variable_1 \rangle \langle init_1 \rangle) \dots),
```

where each (init) is an expression, and (body) is as described in section 11.3.

Semantics: The let* form is similar to let, but the (init)s are evaluated and bindings created sequentially from left to right, with the region of each binding including the bindings to its right as well as \langle body \rangle. Thus the second \langle init \rangle is evaluated in an environment in which the first binding is visible and initialized, and so on.

```
(let ((x 2) (y 3))
 (let* ((x 7)
       (z (+ x y)))
   (* z x)))
                       → 70
```

Note: While the variables bound by a let expression must be distinct, the variables bound by a let* expression need not be distinct.

```
(letrec \langle bindings \rangle \langle body \rangle)
                                                                                      syntax
Syntax: (Bindings) must have the form
       ((\langle variable_1 \rangle \langle init_1 \rangle) \dots),
```

where each (init) is an expression, and (body) is as described in section 11.3. Any variable must not appear more than once in the (variable)s.

Semantics: The (variable)s are bound to fresh locations, the (init)s are evaluated in the resulting environment (in some unspecified order), each (variable) is assigned to the result of the corresponding (init), the (body) is evaluated in the resulting environment, and the values of the last expression in \(body \) are returned. Each binding of a (variable) has the entire letrec expression as its region, making it possible to define mutually recursive procedures.

```
(letrec ((even?
         (lambda (n)
           (if (zero? n)
               #t
               (odd? (- n 1)))))
        (odd?
         (lambda (n)
           (if (zero? n)
               #f
               (even? (- n 1))))))
  (even? 88))
                          \implies #t
```

It should be possible to evaluate each (init) without assigning or referring to the value of any (variable). In the most common uses of letrec, all the (init)s are lambda expressions and the restriction is satisfied automatically. Another restriction is that the continuation of each (init) should not be invoked more than

Implementation responsibilities: Implementations must detect references to a (variable) during the evaluation of the (init) expressions (using one particular evaluation order and order of evaluating the (init) expressions). If an implementation detects such a violation of the restriction, it must raise an exception with condition type &assertion. Implementations may or may not detect that the continuation of each (init) is invoked more than once. However, if the implementation detects this, it must raise an exception with condition type &assertion.

```
(letrec* \langle bindings \rangle \langle body \rangle)
                                                                                      syntax
Syntax: (Bindings) must have the form
       ((\langle variable_1 \rangle \langle init_1 \rangle) \dots),
```

where each (init) is an expression, and (body) is as described in section 11.3. Any variable must not appear more than once in the (variable)s.

Semantics: The (variable)s are bound to fresh locations, each (variable) is assigned in left-to-right order to the result of evaluating the corresponding $\langle \text{init} \rangle$, the $\langle \text{body} \rangle$ is evaluated in the resulting environment, and the values of the last expression in $\langle \text{body} \rangle$ are returned. Despite the left-to-right evaluation and assignment order, each binding of a $\langle \text{variable} \rangle$ has the entire letrec* expression as its region, making it possible to define mutually recursive procedures.

It must be possible to evaluate each $\langle \text{init} \rangle$ without assigning or referring to the value of the corresponding $\langle \text{variable} \rangle$ or the $\langle \text{variable} \rangle$ of any of the bindings that follow it in $\langle \text{bindings} \rangle$. Another restriction is that the continuation of each $\langle \text{init} \rangle$ should not be invoked more than once.

Implementation responsibilities: Implementations must, during the evaluation of an $\langle \text{init} \rangle$ expression, detect references to the value of the corresponding $\langle \text{variable} \rangle$ or the $\langle \text{variable} \rangle$ of any of the bindings that follow it in $\langle \text{bindings} \rangle$. If an implementation detects such a violation of the restriction, it must raise an exception with condition type &assertion. Implementations may or may not detect that the continuation of each $\langle \text{init} \rangle$ is invoked more than once. However, if the implementation detects this, it must raise an exception with condition type &assertion.

```
(let-values \langle mv\text{-}bindings \rangle \langle body \rangle) syntax 
Syntax: \langle Mv\text{-}bindings \rangle must have the form 
((\langle formals_1 \rangle \langle init_1 \rangle) ...),
```

where each $\langle \text{init} \rangle$ is an expression, and $\langle \text{body} \rangle$ is as described in section 11.3. Any variable must not appear more than once in the set of $\langle \text{formals} \rangle$.

Semantics: The $\langle \text{init} \rangle$ s are evaluated in the current environment (in some unspecified order), and the variables occurring in the $\langle \text{formals} \rangle$ are bound to fresh locations containing the values returned by the $\langle \text{init} \rangle$ s, where the $\langle \text{formals} \rangle$ are matched to the return values in the same way that the $\langle \text{formals} \rangle$ in a lambda expression are matched to the arguments in a procedure call. Then, the $\langle \text{body} \rangle$ is evaluated in the extended environment, and the values of the last expression of $\langle \text{body} \rangle$ are returned. Each binding of a variable has $\langle \text{body} \rangle$ as its region. If the $\langle \text{formals} \rangle$ do not match, an exception with condition type &assertion is raised.

```
(let-values (((a b) (values 1 2))

((c d) (values 3 4)))

(list a b c d)) \Longrightarrow (1 2 3 4)
```

```
 \begin{array}{ll} (\texttt{let*-values} \; \langle \textit{mv-bindings} \rangle \; \langle \textit{body} \rangle) & \text{syntax} \\ \textit{Syntax:} \; \langle \texttt{Mv-bindings} \rangle \; \text{must have the form} \\ & (\; (\langle \textit{formals}_1 \rangle \; \langle \textit{init}_1 \rangle) \; \ldots) \; , \end{array}
```

where each $\langle \text{init} \rangle$ is an expression, and $\langle \text{body} \rangle$ is as described in section 11.3. In each $\langle \text{formals} \rangle$, any variable must not appear more than once.

Semantics: The let*-values form is similar to let-values, but the $\langle \text{init} \rangle$ s are evaluated and bindings created sequentially from left to right, with the region of the bindings of each $\langle \text{formals} \rangle$ including the bindings to its right as well as $\langle \text{body} \rangle$. Thus the second $\langle \text{init} \rangle$ is evaluated in an environment in which the bindings of the first $\langle \text{formals} \rangle$ is visible and initialized, and so on.

Note: While all of the variables bound by a let-values expression must be distinct, the variables bound by different (formals) of a let*-values expression need not be distinct.

11.4.7. Sequencing

```
(begin \langle form \rangle \dots)syntax(begin \langle expression \rangle \langle expression \rangle \dots)syntax
```

The \langle begin \rangle keyword has two different roles, depending on its context:

• It may appear as a form in a \langle body \rangle (see section 11.3), \langle (library body) \rangle (see section 7.1), or \langle top-level body \rangle (see chapter 8), or directly nested in a begin form that appears in a body. In this case, the begin form must have the shape specified in the first header line. This use of begin acts as a *splicing* form—the forms inside the \langle body \rangle are spliced into the surrounding body, as if the begin wrapper were not actually present.

A begin form in a $\langle body \rangle$ or $\langle library\ body \rangle$ must be nonempty if it appears after the first $\langle expression \rangle$ within the body.

 It may appear as an ordinary expression and must have the shape specified in the second header line. In this case, the \(\lambda \text{expression} \rangle \text{s are evaluated sequentially from left to right,}\) and the values of the last \(\lambda \text{expression} \rangle \) are returned. This expression type is used to sequence side effects such as assignments or input and output.

```
(define x 0)
(begin (set! x 5)
       (+ \times 1)
(begin (display "4 plus 1 equals ")
       (display (+ 4 1))) \Longrightarrow unspecified
           and prints 4 plus 1 equals 5
```

11.5. Equivalence predicates

A predicate is a procedure that always returns a boolean value (#t or #f). An equivalence predicate is the computational analogue of a mathematical equivalence relation (it is symmetric, reflexive, and transitive). Of the equivalence predicates described in this section, eq? is the finest or most discriminating, and equal? is the coarsest. The eqv? predicate is slightly less discriminating than eq?.

(eqv?
$$obj_1 \ obj_2$$
) procedure

The eqv? procedure defines a useful equivalence relation on objects. Briefly, it returns #t if obj_1 and obj_2 should normally be regarded as the same object and #f otherwise. This relation is left slightly open to interpretation, but the following partial specification of eqv? must hold for all implementations.

The eqv? procedure returns #t if one of the following holds:

- Obj_1 and obj_2 are both booleans and are the same according to the boolean=? procedure (section 11.8).
- Obj_1 and obj_2 are both symbols and are the same according to the symbol=? procedure (section 11.10).
- Obj_1 and obj_2 are both exact number objects and are numerically equal (see =, section 11.7).
- \bullet Obj₁ and obj₂ are both inexact number objects, are numerically equal (see =, section 11.7), and yield the same results (in the sense of eqv?) when passed as arguments to any other procedure that can be defined as a finite composition of Scheme's standard arithmetic procedures.
- \bullet Obj_1 and obj_2 are both characters and are the same character according to the char=? procedure (section 11.11).
- Both obj_1 and obj_2 are the empty list.
- Obj_1 and obj_2 are objects such as pairs, vectors, bytevectors (library chapter ??), strings, hashtables, records (library chapter ??), ports (library section ??), or hashtables (library chapter ??) that refer to the same locations in the store (section 5.10).
- Obj_1 and obj_2 are record-type descriptors that are specified to be eqv? in library section ??.

The eqv? procedure returns #f if one of the following holds:

- Obj_1 and obj_2 are of different types (section 11.1).
- Obj₁ and obj₂ are booleans for which the boolean=? procedure returns #f.
- Obj_1 and obj_2 are symbols for which the symbol=? procedure returns #f.
- One of obj_1 and obj_2 is an exact number object but the other is an inexact number object.
- Obj_1 and obj_2 are rational number objects for which the = procedure returns #f.
- Obj_1 and obj_2 yield different results (in the sense of eqv?) when passed as arguments to any other procedure that can be defined as a finite composition of Scheme's standard arithmetic procedures.
- Obj₁ and obj₂ are characters for which the char=? procedure returns #f.
- One of obj_1 and obj_2 is the empty list, but the other is not.
- Obj_1 and obj_2 are objects such as pairs, vectors, bytevectors (library chapter ??), strings, records (library chapter ??), ports (library section ??), or hashtables (library chapter ??) that refer to distinct locations.
- Obj_1 and obj_2 are pairs, vectors, strings, or records, or hashtables, where the applying the same accessor (i.e. car, cdr, vector-ref, string-ref, or record accessors) to both yields results for which eqv? returns #f.
- Obj_1 and obj_2 are procedures that would behave differently (return different values or have different side effects) for some arguments.

Note: The eqv? procedure returning #t when obj_1 and obj_2 are number objects does not imply that = would also return #t when called with obj_1 and obj_2 as arguments.

```
(eqv? 'a 'a)
                                    #t
(eqv? 'a 'b)
                                    #f
(eqv? 2 2)
                                    #t
(eqv? '() '())
(eqv? 100000000 10000000<del>0)></del> #t
(eqv? (cons 1 2) (cons 1 \stackrel{2}{\Longrightarrow}) #f
(eqv? (lambda () 1)
      (lambda () 2))
                                    #f
(eqv? #f 'nil)
                                    #f
```

The following examples illustrate cases in which the above rules do not fully specify the behavior of eqv?. All that can be said about such cases is that the value returned by eqv? must be a boolean.

```
(let ((p (lambda (x) x)))
 (eqv? p p))
                          ⇒ unspecified
(eqv? "" "")
                               unspecified
(eqv? '#() '#())
                               unspecified
(eqv? (lambda (x) x)
     (lambda (x) x))
                               unspecified
(eqv? (lambda (x) x)
     (lambda (y) y))
                              unspecified
(eqv? +nan.0 +nan.0)
                          ⇒ unspecified
```

The next set of examples shows the use of eqv? with procedures that have local state. Calls to gen-counter must return a distinct procedure every time, since each procedure has its own internal counter. Calls to gen-loser return procedures that behave equivalently when called. However, eqv? may not detect this equivalence.

```
(define gen-counter
 (lambda ()
   (let ((n 0))
     (lambda () (set! n (+ n 1)) n))))
(let ((g (gen-counter)))
 (eqv? g g))
                         ⇒ unspecified
(eqv? (gen-counter) (gen-counter))

⇒ #f
(define gen-loser
 (lambda ()
   (let ((n 0))
     (lambda () (set! n (+ n 1)) 27))))
(let ((g (gen-loser)))

⇒ unspecified

 (eqv? g g))
(eqv? (gen-loser) (gen-loser))
                        ⇒ unspecified
(letrec ((f (lambda () (if (eqv? f g) 'both 'f))) chapter ??), and uses eqv? to compare other nodes.
        (g (lambda () (if (eqv? f g) 'both 'g))))
                         ⇒ unspecified
 (eqv? f q))
(letrec ((f (lambda () (if (eqv? f g) 'f 'both)))
        (g (lambda () (if (eqv? f g) 'g 'both))))
 (eqv? f q))

⇒ #f
```

Implementations may share structure between constants where appropriate. Furthermore, a constant may be copied at any time by the implementation so as to exist simultaneously in different sets of locations, as noted in section 11.4.1. Thus the value of eqv? on constants is sometimes implementation-dependent.

```
(eqv? '(a) '(a))
                                     unspecified
(eqv? "a" "a")
                                     unspecified
                               \Longrightarrow
(eqv? '(b) (cdr '(a b)))\Longrightarrow
                                     unspecified
(let ((x '(a)))
  (eqv? x x))
                                     #t
```

```
(eq? obj_1 \ obj_2)
                                                       procedure
```

The eq? predicate is similar to eqv? except that in some cases it is capable of discerning distinctions finer than those detectable by eqv?.

The eq? and eqv? predicates are guaranteed to have the same behavior on symbols, booleans, the empty list, pairs, procedures, non-empty strings, bytevectors, and vectors, and records. The behavior of eq? on number objects and characters is implementation-dependent, but it always returns either #t or #f, and returns #t only when eqv? would also return #t. The eq? predicate may also behave differently from eqv? on empty vectors, empty bytevectors, and empty strings.

```
(eq? 'a 'a)
                                     #t
(eq? '(a) '(a))
                                     unspecified
                               \Longrightarrow
(eq? (list 'a) (list 'a) \Longrightarrow #f
(eq? "a" "a")

⇒ unspecified
```

```
(eq? "" "")
                           ⇒ unspecified
(eq? '() '())
                                #t
(eq? 2 2)
                                unspecified
(eq? #\A #\A)
                                unspecified
(eq? car car)
                                #t
(let ((n (+ 2 3)))
  (eq? n n))
                                unspecified
(let ((x '(a)))
  (eq? x x))
(let ((x '#()))
  (eq? x x))
                               unspecified
(let ((p (lambda (x) x)))
 (eq? p p))
                               unspecified
```

```
(equal? obj_1 \ obj_2)
                                                   procedure
```

The equal? predicate returns #t if and only if the (possibly infinite) unfoldings of its arguments into regular trees are equal as ordered trees.

The equal? predicate treats pairs and vectors as nodes with outgoing edges, uses string=? to compare strings, uses bytevector=? to compare bytevectors (see library

```
(equal? 'a 'a)
                              #t
(equal? '(a) '(a))
                              #t
(equal? '(a (b) c)
       '(a (b) c))
(equal? "abc" "abc")
(equal? 2 2)
(equal? (make-vector 5 'a)
       (make-vector 5 'a

→
(equal? '#vu8(1 2 3 4 5)
       (u8-list->bytevector
       '(1 2 3 4 5))
(equal? (lambda (x) x)
       (lambda (y) y)) \implies unspecified
(let* ((x (list 'a))
      (y (list 'a))
      (z (list x y)))
  (list (equal? z (list y x))
      (equal? z (list x x))))
         \implies (#t #t)
```

Note: The equal? procedure must always terminate, even if its arguments contain cycles.

11.6. Procedure predicate

```
(procedure? obj)
                                           procedure
```

Returns #t if obj is a procedure, otherwise returns #f.

```
(procedure? car)
(procedure? 'car)
                         \implies #f
(procedure? (lambda (x) (* x x)))
(procedure? '(lambda (x) (* x x)))
```

11.7. Arithmetic

The procedures described here implement arithmetic that is generic over the numerical tower described in chapter 3. The generic procedures described in this section accept both exact and inexact number objects as arguments, performing coercions and selecting the appropriate operations as determined by the numeric subtypes of their arguments.

Library chapter ?? describes libraries that define other numerical procedures.

11.7.1. Propagation of exactness and inexactness

The procedures listed below must return the mathematically correct exact result provided all their arguments are exact:

```
max
           min
                       abs
numerator
           denominator gcd
1cm
           floor
                       ceiling
truncate
            round
                        rationalize
real-part
            imag-part
                        make-rectangular
```

The procedures listed below must return the correct exact result provided all their arguments are exact, and no divisors are zero:

Moreover, the procedure expt must return the correct exact result provided its first argument is an exact real number object and its second argument is an exact integer object.

The general rule is that the generic operations return the correct exact result when all of their arguments are exact and the result is mathematically well-defined, but return an inexact result when any argument is inexact. Exceptions to this rule include sgrt, exp, log, sin, cos, tan, asin, acos, atan, expt, make-polar, magnitude, and angle, which may (but are not required to) return inexact results even when given exact arguments, as indicated in the specification of these procedures.

One general exception to the rule above is that an implementation may return an exact result despite inexact arguments if that exact result would be the correct result for all possible substitutions of exact arguments for the inexact ones. An example is (* 1.0 0) which may return either 0 (exact) or 0.0 (inexact).

11.7.2. Representability of infinities and NaNs

The specification of the numerical operations is written as though infinities and NaNs are representable, and specifies many operations with respect to these number objects in ways that are consistent with the IEEE-754 standard for binary floatingpoint arithmetic. An implementation of Scheme may or may not represent infinities and NaNs; however, an implementation must raise a continuable exception with condition type &no-infinities or &no-nans (respectively; see library

section ??) whenever it is unable to represent an infinity or NaN as specified. In this case, the continuation of the exception handler is the continuation that otherwise would have received the infinity or NaN value. This requirement also applies to conversions between number objects and external representations, including the reading of program source code.

11.7.3. Semantics of common operations

Some operations are the semantic basis for several arithmetic procedures. The behavior of these operations is described in this section for later reference.

Integer division

Scheme's operations for performing integer division rely on mathematical operations div, mod, div_0 , and mod_0 , that are defined as follows:

 div , mod , div_0 , and mod_0 each accept two real numbers x_1 and x_2 as operands, where x_2 must be nonzero.

div returns an integer, and mod returns a real. Their results are specified by

$$x_1 \operatorname{div} x_2 = n_d$$

$$x_1 \operatorname{mod} x_2 = x_m$$

where

$$x_1 = n_d \cdot x_2 + x_m$$
$$0 \le x_m < |x_2|$$

Examples:

$$123 \operatorname{div} 10 = 12$$

$$123 \operatorname{mod} 10 = 3$$

$$123 \operatorname{div} -10 = -12$$

$$123 \operatorname{mod} -10 = 3$$

$$-123 \operatorname{div} 10 = -13$$

$$-123 \operatorname{mod} 10 = 7$$

$$-123 \operatorname{div} -10 = 13$$

$$-123 \operatorname{mod} -10 = 7$$

 div_0 and mod_0 are like div and mod, except the result of mod_0 lies within a half-open interval centered on zero. The results are specified by

$$x_1 \operatorname{div}_0 x_2 = n_d$$

$$x_1 \operatorname{mod}_0 x_2 = x_m$$

where:

$$\begin{array}{l} x_1 = n_d \cdot x_2 + x_m \\ - \left| \frac{x_2}{2} \right| \leq x_m < \left| \frac{x_2}{2} \right| \end{array}$$

Examples:

$$123 \operatorname{div}_0 10 = 12$$

 $123 \operatorname{mod}_0 10 = 3$

Transcendental functions

In general, the transcendental functions \log , \sin^{-1} (arcsine), \cos^{-1} (arccosine), and \tan^{-1} are multiply defined. The value of $\log z$ is defined to be the one whose imaginary part lies in the range from $-\pi$ (inclusive if -0.0 is distinguished, exclusive otherwise) to π (inclusive). $\log 0$ is undefined.

The value of $\log z$ for non-real z is defined in terms of \log on real numbers as

$$\log z = \log |z| + (\text{angle } z)i$$

where angle z is the angle of $z = a \cdot e^{ib}$ specified as:

angle
$$z = b + 2\pi n$$

with $-\pi \leq \text{angle } z \leq \pi$ and $\text{angle } z = b + 2\pi n$ for some integer n.

With the one-argument version of log defined this way, the values of the two-argument-version of log, $\sin^{-1} z$, $\cos^{-1} z$, $\tan^{-1} z$, and the two-argument version of \tan^{-1} are according to the following formulæ:

$$\log z \, b = \frac{\log z}{\log b}$$

$$\sin^{-1} z = -i \log(iz + \sqrt{1 - z^2})$$

$$\cos^{-1} z = \pi/2 - \sin^{-1} z$$

$$\tan^{-1} z = (\log(1 + iz) - \log(1 - iz))/(2i)$$

$$\tan^{-1} x \, y = \operatorname{angle}(x + yi)$$

The range of $\tan^{-1} x y$ is as in the following table. The asterisk (*) indicates that the entry applies to implementations that distinguish minus zero.

	y condition	x condition	range of result r
	y = 0.0	x > 0.0	0.0
*	y = +0.0	x > 0.0	+0.0
*	y = -0.0	x > 0.0	-0.0
	y > 0.0	x > 0.0	$0.0 < r < \frac{\pi}{2}$
	y > 0.0	x = 0.0	$\frac{\frac{\pi}{2}}{\frac{\pi}{2}} < r < \pi$
	y > 0.0	x < 0.0	$\frac{\pi}{2} < r < \pi$
	y = 0.0	x < 0	$\tilde{\pi}$
*	y = +0.0	x < 0.0	π
*	y = -0.0	x < 0.0	$-\pi$
	y < 0.0	x < 0.0	$-\pi < r < -\frac{\pi}{2}$
	y < 0.0	x = 0.0	$-\frac{\pi}{2} - \frac{\pi}{2} < r < 0.0$
	y < 0.0	x > 0.0	$-\frac{\pi}{2} < r < 0.0$
	y = 0.0	x = 0.0	undefined
*	y = +0.0	x = +0.0	+0.0
*	y = -0.0	x = +0.0	-0.0
*	y = +0.0	x = -0.0	π
*	y = -0.0	x = -0.0	$-\pi$
*	y = +0.0	x = 0	$\frac{\pi}{2}$
*	y = -0.0	x = 0	$\frac{2}{\pi}\frac{\pi}{2}$

11.7.4. Numerical operations

Numerical type predicates

(number? obj)	procedure
(complex? obj)	procedure
(real? obj)	procedure
(rational? obj)	procedure
(integer? obj)	procedure

These numerical type predicates can be applied to any kind of argument. They return #t if the object is a number object of the named type, and #f otherwise. In general, if a type predicate is true of a number object then all higher type predicates are also true of that number object. Consequently, if a type predicate is false of a number object, then all lower type predicates are also false of that number object.

If z is a complex number object, then (real? z) is true if and only if (zero? (imag-part z)) and (exact? (imag-part z)) are both true.

If x is a real number object, then (rational? x) is true if and only if there exist exact integer objects k_1 and k_2 such that (= x (/ k_1 k_2)) and (= (numerator x) k_1) and (= (denominator x) k_2) are all true. Thus infinities and NaNs are not rational number objects.

If q is a rational number objects, then (integer? q) is true if and only if (= (denominator q) 1) is true. If q is not a rational number object, then (integer? q) is #f.

```
\begin{array}{llll} (\text{complex? 3+4i}) & \Longrightarrow & \text{\#t} \\ (\text{complex? 3}) & \Longrightarrow & \text{\#t} \\ (\text{real? 3}) & \Longrightarrow & \text{\#t} \\ (\text{real? -2.5+0.0i}) & \Longrightarrow & \text{\#f} \\ (\text{real? -2.5+0i}) & \Longrightarrow & \text{\#t} \\ (\text{real? -2.5}) & \Longrightarrow & \text{\#t} \\ (\text{real? \#e1e10}) & \Longrightarrow & \text{\#t} \\ \end{array}
```

```
(rational? 6/10)
                         \implies #t
(rational? 6/3)
                             #t
(rational? 2)
                             #t
(integer? 3+0i)

    #t
(integer? 3.0)
                         \implies #t
(integer? 8/4)
                             # t.
(number? +nan.0)
                         \implies #t
(complex? +nan.0)
(real? +nan.0)

    #t
(rational? +nan.0)

    # f
(complex? +inf.0)
                         (real? -inf.0)
                         \implies #t
(rational? -inf.0)
                         \implies #f
(integer? -inf.0)
```

Note: Except for number?, the behavior of these type predicates on inexact number objects is unreliable, because any inaccuracy may affect the result.

```
(real-valued? obj)
                                          procedure
(rational-valued? obj)
                                         procedure
(integer-valued? obj)
                                         procedure
```

These numerical type predicates can be applied to any kind of argument. The real-valued? procedure returns #t if the object is a number object and is equal in the sense of = to some real number object, or if the object is a NaN, or a complex number object whose real part is a NaN and whose imaginary part is zero in the sense of zero?. The rational-valued? and integer-valued? procedures return #t if the object is a number object and is equal in the sense of = to some object of the named type, and otherwise they return #f.

```
(real-valued? +nan.0)
(real-valued? +nan.0+0i) ⇒ #t
(real-valued? -inf.0) ⇒ #t
(real-valued? 3)

    # +

(real-valued? -2.5+0.0i) \Longrightarrow
                             # t.
(real-valued? -2.5+0i) \implies
                             # t.
(real-valued? -2.5)
(real-valued? #e1e10) \implies #t
(rational-valued? +nan.0⇒ #f
(rational-valued? -inf.0→ #f
(rational-valued? 6/10) \implies #t
(rational-valued? 6/10+0-0i) #t
(rational-valued? 6/10+0+→ #t
(rational-valued? 6/3) \implies #t
(integer-valued? 3+0i) \implies #t
(integer-valued? 3+0.0i)⇒ #t
(integer-valued? 3.0) \implies #t
(integer-valued? 3.0+0.0 ≠ #t
(integer-valued? 8/4) \implies #t
```

Note: These procedures test whether a given number object can be coerced to the specified type without loss of numerical accuracy. Specifically, the behavior of these predicates differs from the behavior of real?, rational?, and integer? on complex number objects whose imaginary part is inexact zero.

Note: The behavior of these type predicates on inexact number objects is unreliable, because any inaccuracy may affect the result.

```
(exact? z)
                                            procedure
                                            procedure
(inexact? z)
```

These numerical predicates provide tests for the exactness of a quantity. For any number object, precisely one of these predicates is true.

```
(exact? 5)
(inexact? +inf.0)
```

Generic conversions

```
procedure
(inexact z)
                                            procedure
(exact z)
```

The inexact procedure returns an inexact representation of z. If inexact number objects of the appropriate type have bounded precision, then the value returned is an inexact number object that is nearest to the argument. If an exact argument has no reasonably close inexact equivalent, an exception with condition type &implementation-violation may be raised.

Note: For a real number object whose magnitude is finite but so large that it has no reasonable finite approximation as an inexact number, a reasonably close inexact equivalent may be +inf.0 or -inf.0. Similarly, the inexact representation of a complex number object whose components are finite may have infinite components.

The exact procedure returns an exact representation of z. The value returned is the exact number object that is numerically closest to the argument; in most cases, the result of this procedure should be numerically equal to its argument. If an inexact argument has no reasonably close exact equivalent, an exception with condition type &implementation-violation may be raised.

These procedures implement the natural one-to-one correspondence between exact and inexact integer objects throughout an implementation-dependent range.

The inexact and exact procedures are idempotent.

Arithmetic operations

```
(= z_1 \ z_2 \ z_3 \ \dots)
                                                                  procedure
(< x_1 \ x_2 \ x_3 \ \dots)
                                                                  procedure
(> x_1 \ x_2 \ x_3 \ \dots)
                                                                  procedure
                                                                  procedure
(<= x_1 \ x_2 \ x_3 \ \dots)
(>= x_1 \ x_2 \ x_3 \dots)
                                                                  procedure
```

These procedures return #t if their arguments are (respectively): equal, monotonically increasing, monotonically decreasing, monotonically nondecreasing, or monotonically nonincreasing, and #f otherwise.

44 Revised⁶ Scheme

For any real number object x that is neither infinite nor NaN:

```
(< -inf.0 \ x + inf.0)) \implies #t
(> +inf.0 \ x - inf.0)) \implies #t
```

For any number object *z*:

```
(= +nan.0 z) \implies #f
```

For any real number object *x*:

```
(< +nan.0 x) \Longrightarrow #f (> +nan.0 x) \Longrightarrow #f
```

These predicates must be transitive.

Note: The traditional implementations of these predicates in Lisp-like languages are not transitive.

Note: While it is possible to compare inexact number objects using these predicates, the results may be unreliable because a small inaccuracy may affect the result; this is especially true of = and zero? (below).

When in doubt, consult a numerical analyst.

```
(zero? z)
                                            procedure
                                            procedure
(positive? x)
                                            procedure
(negative? x)
                                            procedure
(odd? n)
                                            procedure
(even? n)
                                            procedure
(finite? x)
(infinite? x)
                                            procedure
(nan? x)
                                            procedure
```

These numerical predicates test a number object for a particular property, returning #t or #f. The zero? procedure tests if the number object is = to zero, positive? tests whether it is greater than zero, negative? tests whether it is less than zero, odd? tests whether it is odd, even? tests whether it is even, finite? tests whether it is not an infinity and not a NaN, infinite? tests whether it is an infinity, nan? tests whether it is a NaN.

```
(zero? +0.0)

    #t
(zero? -0.0)
                                     #t
(zero? +nan.0)
                               \implies #f
(positive? +inf.0)
                               \implies #t
(negative? -inf.0)
                               \implies #t
(positive? +nan.0)

(infinite? +inf.0)

    # t.
```

Note: As with the predicates above, the results may be unreliable because a small inaccuracy may affect the result.

```
(\max x_1 \ x_2 \dots) procedure (\min x_1 \ x_2 \dots) procedure
```

These procedures return the maximum or minimum of their arguments.

```
(\max 3 4) \qquad \Longrightarrow 4
(\max 3.9 4) \qquad \Longrightarrow 4.0
```

For any real number object *x*:

```
(\max + \inf.0 x) \Longrightarrow +\inf.0
(\min -\inf.0 x) \Longrightarrow -\inf.0
```

Note: If any argument is inexact, then the result is also inexact (unless the procedure can prove that the inaccuracy is not large enough to affect the result, which is possible only in unusual implementations). If min or max is used to compare number objects of mixed exactness, and the numerical value of the result cannot be represented as an inexact number object without loss of accuracy, then the procedure may raise an exception with condition type &implementation-restriction.

```
(+ z_1 \ldots) procedure (* z_1 \ldots) procedure
```

These procedures return the sum or product of their arguments.

```

                             \implies 0 or 0.0
```

For any real number object *x* that is neither infinite nor NaN:

```
(+ + \inf.0 x) \implies + \inf.0
(+ -\inf.0 x) \implies -\inf.0
```

For any real number object *x*:

```
(+ + \text{nan.0 } x) \implies + \text{nan.0}
```

For any real number object x that is not an exact 0:

```
(* + nan.0 x) \implies +nan.0
```

If any of these procedures are applied to mixed non-rational real and non-real complex arguments, they either raise an exception with condition type &implementation-restriction or return an unspecified number object.

Implementations that distinguish -0.0 should adopt behavior consistent with the following examples:

```
 \begin{array}{cccc} (+\ 0.0\ -0.0) & \Longrightarrow 0.0 \\ (+\ -0.0\ 0.0) & \Longrightarrow 0.0 \\ (+\ 0.0\ 0.0) & \Longrightarrow 0.0 \\ (+\ -0.0\ -0.0) & \Longrightarrow -0.0 \\ \end{array}
```

```
(-z)
                                                procedure
                                                procedure
(-z_1 z_2 ...)
```

With two or more arguments, this procedures returns the difference of its arguments, associating to the left. With one argument, however, it returns the additive inverse of its argument.

```
(-34)
(- 3 4 5)
(- 3)

→ -6
(-+\inf.0+\inf.0) \implies +nan.0
```

If this procedure is applied to mixed non-rational real and non-real complex arguments, it either raises an exception with condition type &implementation-restriction or returns an unspecified number object.

Implementations that distinguish -0.0 should adopt behavior consistent with the following examples:

```
(-0.0)
                                  \implies -0.0
(-0.0)

```
(div-and-mod x_1 x_2)
                                                          procedure
                                                          procedure
(\text{div } x_1 \ x_2)
                                                          procedure
(\text{mod } x_1 \ x_2)
(div0-and-mod0 x_1 x_2)
                                                          procedure
                                                          procedure
(\text{div0} x_1 x_2)
                                                          procedure
(\text{mod0} x_1 x_2)
```

These procedures implement number-theoretic integer division and return the results of the corresponding mathematical operations specified in section 11.7.3. In each case, x_1 must be neither infinite nor a NaN, and x_2 must be nonzero; otherwise, an exception with condition type &assertion is raised.

```
\implies x_1 \text{ div } x_2
(\text{div } x_1 \ x_2)
(\text{mod } x_1 \ x_2)
                                           \implies x_1 \mod x_2
(div-and-mod x_1 x_2)
                                        \implies x_1 \operatorname{div} x_2, x_1 \operatorname{mod} x_2
                                           ; two return values
                                          \implies x_1 \operatorname{div}_0 x_2
(\text{div0} x_1 x_2)
(\text{mod0} \ x_1 \ x_2)
                                          \implies x_1 \mod_0 x_2
(div0-and-mod0 x_1 x_2)
              \implies x_1 \operatorname{div}_0 x_2, x_1 \operatorname{mod}_0 x_2
                                           ; two return values
```

```
(\gcd n_1 \ldots)
                                                      procedure
(lcm n_1 \dots)
                                                      procedure
```

These procedures return the greatest common divisor or least common multiple of their arguments. The result is always nonnegative.

```
(gcd 32 -36)
                             \implies 4
(gcd)
(lcm 32 -36)
(lcm 32.0 -36)
                             \implies 0
                             ⇒ 288
                             ⇒ 288.0
(1cm)
```

```
(numerator q)
                                          procedure
(denominator q)
                                          procedure
```

These procedures return the numerator or denominator of their argument; the result is computed as if the argument was represented as a fraction in lowest terms. The denominator is always positive. The denominator of 0 is defined to be 1.

```
(numerator (/ 6 4))
                         \implies 2
(denominator (/ 6 4))
(denominator
 (inexact (/ 6 4))) \implies 2.0
```

```
(floor x)
                                           procedure
                                           procedure
(ceiling x)
(truncate x)
                                           procedure
(round x)
                                           procedure
```

These procedures return inexact integer objects for inexact arguments that are not infinities or NaNs, and exact integer objects for exact rational arguments. For such arguments, floor returns the largest integer object not larger than x. The ceiling procedure returns the smallest integer object not smaller than x. The truncate procedure returns the integer object closest to x whose absolute value is not larger than the absolute value of x. The round procedure returns the closest integer object to x, rounding to even when x represents a number halfway between two integers.

Note: If the argument to one of these procedures is inexact, then the result is also inexact. If an exact value is needed, the result should be passed to the exact procedure.

Although infinities and NaNs are not integer objects, these procedures return an infinity when given an infinity as an argument, and a NaN when given a NaN.

```

                         \implies -inf.0
(ceiling -inf.0)
(round +nan.0)
                         \implies +nan.0
```

```
(rationalize x_1 x_2) procedure
```

The rationalize procedure returns the a number object representing the *simplest* rational number differing from x_1 by no more than x_2 . A rational number r_1 is *simpler* than another rational number r_2 if $r_1 = p_1/q_1$ and $r_2 = p_2/q_2$ (in lowest terms) and $|p_1| \leq |p_2|$ and $|q_1| \leq |q_2|$. Thus 3/5 is simpler than 4/7. Although not all rationals are comparable in this ordering (consider 2/7 and 3/5) any interval contains a rational number that is simpler than every other rational number in that interval (the simpler 2/5 lies between 2/7 and 3/5). Note that 0 = 0/1 is the simplest rational of all.

```
\begin{array}{c} (\text{rationalize (exact .3) 1/10}) \\ \Longrightarrow 1/3 \\ (\text{rationalize .3 1/10}) \\ \Longrightarrow \#i1/3 \; ; \; \text{approximately} \\ (\text{rationalize +inf.0 3}) \Longrightarrow +inf.0 \\ (\text{rationalize +inf.0 +inf} \mapsto +nan.0 \\ (\text{rationalize 3 +inf.0}) \Longrightarrow 0.0 \\ \end{array}
```

The first two examples hold only in implementations whose inexact real number objects have sufficient precision.

```
procedure
(exp z)
                                                 procedure
(\log z)
                                                 procedure
(\log z_1 z_2)
                                                 procedure
(\sin z)
                                                 procedure
(\cos z)
                                                 procedure
(tan z)
                                                 procedure
(asin z)
                                                 procedure
(acos z)
```

```
 \begin{array}{ll} \text{(atan } z) & \text{procedure} \\ \text{(atan } x_1 \ x_2) & \text{procedure} \end{array}
```

These procedures compute the usual transcendental functions. The exp procedure computes the base-e exponential of z. The log procedure with a single argument computes the natural logarithm of z (not the base-ten logarithm); (log z_1 z_2) computes the base- z_2 logarithm of z_1 . The asin, acos, and atan procedures compute arcsine, arccosine, and arctangent, respectively. The two-argument variant of atan computes (angle (make-rectangular x_2 x_1)).

See section 11.7.3 for the underlying mathematical operations. These procedures may return inexact results even when given exact arguments.

```
(exp + inf.0)
                           \implies +inf.0
(exp -inf.0)

         ; if -0.0 is distinguished
```

```
(\text{sqrt } z) procedure
```

Returns the principal square root of z. For rational z, the result has either positive real part, or zero real part and non-negative imaginary part. With log defined as in section 11.7.3, the value of (sqrt z) could be expressed as $e^{\frac{\log z}{2}}$.

The sqrt procedure may return an inexact result even when given an exact argument.

```
(\operatorname{sqrt} -5) \\ \Longrightarrow 0.0+2.23606797749979i ; approximately \\ (\operatorname{sqrt} + \operatorname{inf.0}) \\ (\operatorname{sqrt} - \operatorname{inf.0}) \\ \Longrightarrow + \operatorname{inf.0}i
```

```
(exact-integer-sqrt k) procedure
```

The exact-integer-sqrt procedure returns two non-negative exact integer objects s and r where $k = s^2 + r$ and $k < (s+1)^2$.

```
(expt z_1 z_2)
                                                   procedure
```

Returns z_1 raised to the power z_2 . For nonzero z_1 , this is $e^{z_2 \log z_1}$. 0.0^z is 1.0 if z = 0.0, and 0.0 if (real-part z) is positive. For other cases in which the first argument is zero, either an exception is raised with condition type &implementationrestriction, or an unspecified number object is returned.

For an exact real number object z_1 and an exact integer object z_2 , (expt z_1 z_2) must return an exact result. For all other values of z_1 and z_2 , (expt z_1 z_2) may return an inexact result, even when both z_1 and z_2 are exact.

```

```

Suppose a_1 , a_2 , a_3 , and a_4 are real numbers, and c is a complex number such that the following holds:

$$c = a_1 + a_2 i = a_3 e^{ia_4}$$

Then, if x_1 , x_2 , x_3 , and x_4 are number objects representing a_1 , a_2 , a_3 , and a_4 , respectively, (make-rectangular x_1 x_2) returns c, and (make-polar x_3 x_4) returns c.

```
(make-rectangular 1.1 2.2)
        \implies 1.1+2.2i; approximately
(make-polar 1.1 2.2)
         \implies 1.102.2; approximately
```

Conversely, if $-\pi \le a_4 \le \pi$, and if z is a number object representing c, then (real-part z) returns a_1 (imagpart z) returns a_2 , (magnitude z) returns a_3 , and (angle z) returns a_4 .

```
(real-part 1.1+2.2i) \implies 1.1; approximately
(imag-part 1.1+2.2i) \implies 2.2i; approximately
(magnitude 1.102.2) \implies 1.1; approximately
(angle 1.1@2.2)
                         \implies 2.2; approximately
(angle -1.0)
         \implies 3.141592653589793; approximately
(angle -1.0+0.0i)
         \implies 3.141592653589793; approximately
(angle -1.0-0.0i)
         \implies -3.141592653589793; approximately
         ; if -0.0 is distinguished
(angle +inf.0)
(angle -inf.0)
         \implies 3.141592653589793; approximately
```

Moreover, suppose x_1 , x_2 are such that either x_1 or x_2 is an infinity, then

```
(\text{make-rectangular } x_1 \ x_2) \implies z
(magnitude z)
                                 \implies +inf.0
```

The make-polar, magnitude, and angle procedures may return inexact results even when given exact arguments.

```
(angle -1)
         \implies 3.141592653589793; approximately
```

Numerical Input and Output

```
(number->string z)
                                          procedure
(number->string z radix)
                                          procedure
(number->string z radix precision)
                                          procedure
```

Radix must be an exact integer object, either 2, 8, 10, or 16. If omitted, radix defaults to 10. If a precision is specified, then z must be an inexact complex number object, precision must be an exact positive integer object, and radix must be 10. The number->string procedure takes a number object and a radix and returns as a string an external representation of the given number object in the given radix such that

```
(let ((number z) (radix radix))
 (eqv? (string->number
        (number->string number radix)
        radix)
      number))
```

is true. If no possible result makes this expression true, an exception with condition type &implementationrestriction is raised.

Note: The error case can occur only when z is not a complex number object or is a complex number object with a non-rational real or imaginary part.

If a *precision* is specified, then the representations of the inexact real components of the result, unless they are infinite or NaN, specify an explicit (mantissa width) p, and p is the least $p \ge 1$ precision for which the above expression is true.

If z is inexact, the radix is 10, and the above expression and condition can be satisfied by a result that contains a decimal point, then the result contains a decimal point and is expressed using the minimum number of digits (exclusive of exponent, trailing zeroes, and mantissa width) needed to make the above expression and condition true [?, ?]; otherwise the format of the result is unspecified.

The result returned by number->string never contains an explicit radix prefix.

```
procedure
(string->number string)
                                           procedure
(string->number string radix)
```

Returns a number object with maximally precise representation expressed by the given string. Radix must be an exact integer object, either 2, 8, 10, or 16. If supplied, *radix* is a default radix that may be overridden by an explicit radix prefix in string (e.g., "#0177"). If *radix* is not supplied, then the default radix is 10. If *string* is not a syntactically valid notation for a number object or a notation for a rational number object with a zero denominator, then string->number returns #f.

```
\begin{array}{lll} (\text{string-} > \text{number "100"}) & \Longrightarrow & 100 \\ (\text{string-} > \text{number "100" 16} \Longrightarrow & 256 \\ (\text{string-} > \text{number "1e2"}) & \Longrightarrow & 100.0 \\ (\text{string-} > \text{number "0/0"}) & \Longrightarrow & \#f \\ (\text{string-} > \text{number "+inf.0"} \Longrightarrow & +\text{inf.0} \\ (\text{string-} > \text{number "-inf.0"} \Longrightarrow & -\text{inf.0} \\ (\text{string-} > \text{number "+nan.0"} \Longrightarrow & +\text{nan.0} \end{array}
```

Note: The string->number procedure always returns a number object or #f; it never raises an exception.

11.8. Booleans

The standard boolean objects for true and false have external representations #t and #f. However, of all objects, only #f counts as false in conditional expressions. See section 5.7.

Note: Programmers accustomed to other dialects of Lisp should be aware that Scheme distinguishes both #f and the empty list from each other and from the symbol nil.

```
(not obj) procedure
```

Returns #t if obj is #f, and returns #f otherwise.

```
\begin{array}{lll} (\text{not } \#\text{t}) & \Longrightarrow & \#\text{f} \\ (\text{not } 3) & \Longrightarrow & \#\text{f} \\ (\text{not } (\text{list } 3)) & \Longrightarrow & \#\text{f} \\ (\text{not } \#\text{f}) & \Longrightarrow & \#\text{t} \\ (\text{not } '()) & \Longrightarrow & \#\text{f} \\ (\text{not } (\text{list})) & \Longrightarrow & \#\text{f} \\ (\text{not } '\text{nil}) & \Longrightarrow & \#\text{f} \end{array}
```

```
(boolean? obj) procedure
```

Returns #t if *obj* is either #t or #f and returns #f otherwise.

```
\begin{array}{lll} \mbox{(boolean? $\# f$)} & \Longrightarrow & \# t \\ \mbox{(boolean? $0$)} & \Longrightarrow & \# f \\ \mbox{(boolean? $'()$)} & \Longrightarrow & \# f \end{array}
```

```
(boolean=? bool_1 \ bool_2 \ bool_3 \dots) procedure
```

Returns #t if the booleans are the same.

11.9. Pairs and lists

A *pair* is a compound structure with two fields called the car and cdr fields (for historical reasons). Pairs are created by the procedure cons. The car and cdr fields are accessed by the procedures car and cdr.

Pairs are used primarily to represent lists. A list can be defined recursively as either the empty list or a pair whose cdr is a list. More precisely, the set of lists is defined as the smallest set *X* such that

- The empty list is in X.
- If list is in X, then any pair whose cdr field contains list is also in X.

The objects in the car fields of successive pairs of a list are the elements of the list. For example, a two-element list is a pair whose car is the first element and whose cdr is a pair whose car is the second element and whose cdr is the empty list. The length of a list is the number of elements, which is the same as the number of pairs.

The empty list is a special object of its own type. It is not a pair. It has no elements and its length is zero.

Note: The above definitions imply that all lists have finite length and are terminated by the empty list.

A chain of pairs not ending in the empty list is called an *improper list*. Note that an improper list is not a list. The list and dotted notations can be combined to represent improper lists:

```
(a b c . d)
```

```
is equivalent to
```

(a . (b . (c . d)))

Whether a given pair is a list depends upon what is stored in the cdr field.

```
(pair? obj) procedure
```

Returns #t if obj is a pair, and otherwise returns #f.

```
(cons obj_1 obj_2) procedure
```

Returns a newly allocated pair whose car is obj_1 and whose cdr is obj_2 . The pair is guaranteed to be different (in the sense of eqv?) from every existing object.

```
\begin{array}{llll} (\text{cons 'a ' ()}) & \Longrightarrow & \text{(a)} \\ (\text{cons ' (a) ' (b c d)}) & \Longrightarrow & \text{((a) b c d)} \\ (\text{cons "a" ' (b c)}) & \Longrightarrow & \text{("a" b c)} \\ (\text{cons 'a 3)} & \Longrightarrow & \text{(a . 3)} \\ (\text{cons ' (a b) 'c)} & \Longrightarrow & \text{((a b) . c)} \end{array}
```

```
(car pair) procedure
```

Returns the contents of the car field of *pair*.

```
\begin{array}{lll} (\text{car } ' (\text{a b c})) & \Longrightarrow & \text{a} \\ (\text{car } ' ((\text{a}) \text{ b c d})) & \Longrightarrow & \text{(a)} \\ (\text{car } ' (1 \ . \ 2)) & \Longrightarrow & 1 \\ (\text{car } ' ()) & \Longrightarrow & \text{&assertion } \textit{exception} \end{array}
```

```
(cdr pair) procedure
```

Returns the contents of the cdr field of pair.

```
(cdr '((a) b c d))
                         \implies (b c d)
(cdr '(1 . 2))
                          \implies 2
(cdr '())
                         ⇒ &assertion exception
```

```
procedure
(caar pair)
(cadr pair)
                                              procedure
(cdddar pair)
                                              procedure
                                              procedure
(cddddr pair)
```

These procedures are compositions of car and cdr, where for example caddr could be defined by

Arbitrary compositions, up to four deep, are provided. There are twenty-eight of these procedures in all.

```
(null? obj)
                                              procedure
```

Returns #t if *obj* is the empty list, #fotherwise.

```
(list? obj)
                                              procedure
```

Returns #t if obj is a list, #f otherwise. By definition, all lists are chains of pairs that have finite length and are terminated by the empty list.

```
(list? '(a b c))
                        \implies #t
(list? '())

    #t
(list? '(a . b))

    #f
```

```
(list obj ...)
                                               procedure
```

Returns a newly allocated list of its arguments.

```
(list 'a (+ 3 4) 'c)
                                      (a 7 c)
                                 \Longrightarrow
(list)
                                 \implies ()
```

```
(length list)
                                                procedure
```

Returns the length of list.

```
(length '(a b c))
(length '(a (b) (c d e)) \Longrightarrow
(length '())
```

```
(append list \dots obj)
                                                  procedure
```

Returns a possibly improper list consisting of the elements of the first *list* followed by the elements of the other *list*s, with *obj* as the cdr of the final pair. An improper list results if obj is not a list.

```
(append '(x) '(y))
                             \implies (x y)
(append '(a) '(b c d)) \implies (a b c d)
(append '(a (b)) '((c))) \Longrightarrow (a (b) (c))
(append '(a b) '(c . d)) \Longrightarrow (a b c . d)
(append '() 'a)
                             \implies a
```

If append constructs a nonempty chain of pairs, it is always newly allocated. If no pairs are allocated, *obj* is returned.

```
(reverse list)
                                              procedure
```

Returns a newly allocated list consisting of the elements of list in reverse order.

```
(reverse '(a b c))
                          \implies (c b a)
(reverse '(a (b c) d (e (f))))
        \implies ((e (f)) d (b c) a)
```

```
(list-tail list k)
                                             procedure
```

(define caddr (lambda (x) (car (cdr (cdr x))))). List should be a list of size at least k. The list-tail procedure returns the subchain of pairs of list obtained by omitting the first k elements.

```
(list-tail '(a b c d) 2) \Longrightarrow (c d)
```

Implementation responsibilities: The implementation must check that *list* is a chain of pairs whose length is at least k. It should not check that it is a chain of pairs beyond this length.

```
(list-ref list k)
                                             procedure
```

List must be a list whose length is at least k + 1. The listtail procedure returns the *k*th element of *list*.

```
(list-ref '(a b c d) 2) \Longrightarrow c
```

Implementation responsibilities: The implementation must check that *list* is a chain of pairs whose length is at least k + 1. It should not check that it is a list of pairs beyond this length.

```
(map proc list_1 list_2 ...)
                                                     procedure
```

The *lists* should all have the same length. *Proc* should accept as many arguments as there are *lists* and return a single value. *Proc* should not mutate any of the *lists*.

The map procedure applies *proc* element-wise to the elements of the *list*s and returns a list of the results, in order. *Proc* is always called in the same dynamic environment as map itself. The order in which *proc* is applied to the elements of the *lists* is unspecified. If multiple returns occur from map, the values returned by earlier returns are not mutated.

```
(map cadr '((a b) (d e) (g h)))
         \implies (b e h)
(map (lambda (n) (expt n n))
    '(1 2 3 4 5))
         \implies (1 4 27 256 3125)
(map + '(1 2 3) '(4 5 6)) \Longrightarrow (5 7 9)
(let ((count 0))
 (map (lambda (ignored)
        (set! count (+ count 1))
        count.)
      '(a b)))
                           \implies (1 2) or (2 1)
```

Implementation responsibilities: The implementation should check that the *lists* all have the same length. The implementation must check the restrictions on proc to the extent performed by applying it as described. An implementation may check whether *proc* is an appropriate argument before applying it.

```
(for-each proc \ list_1 \ list_2 \dots)
                                                        procedure
```

The *list*s should all have the same length. *Proc* should accept as many arguments as there are *lists*. *Proc* should not mutate any of the lists.

The for-each procedure applies proc element-wise to the elements of the *lists* for its side effects, in order from the first elements to the last. Proc is always called in the same dynamic environment as for-each itself. The return values of foreach are unspecified.

```
(let ((v (make-vector 5)))
 (for-each (lambda (i)
            (vector-set! v i (* i i)))
          '(0 1 2 3 4))
 v)
                         \implies # (0 1 4 9 16)
(for-each (lambda (x) x) '(1 2 3 4))
        ⇒ unspecified
(for-each even? '())
                         ⇒ unspecified
```

Implementation responsibilities: The implementation should check that the *lists* all have the same length. The implementation must check the restrictions on proc to the extent performed by applying it as described. An implementation may check whether *proc* is an appropriate argument before applying it.

Note: Implementations of for-each may or may not tail-call proc on the last elements.

11.10. Symbols

Symbols are objects whose usefulness rests on the fact that two symbols are identical (in the sense of eq?, eqv? and equal?) if and only if their names are spelled the same way. A symbol literal is formed using quote.

```
(symbol? obj)
                                             procedure
```

Returns #t if *obj* is a symbol, otherwise returns #f.

```
(symbol? 'foo)
(symbol? (car ' (a b))) \Longrightarrow #t
(symbol? "bar")

⇒ # f
(symbol? 'nil)
(symbol? '())

⇒ #f
(symbol? #f)
```

```
(symbol->string symbol)
                                          procedure
```

Returns the name of *symbol* as an immutable string.

```
(symbol->string 'flying-fish)
                        ⇒ "flying-fish"
(symbol->string 'Martin) → "Martin"
(symbol->string
  (string->symbol "Malvina"))
                        \Longrightarrow "Malvina"
```

```
(symbol=? symbol_1 \ symbol_2 \ symbol_3 \dots)
                                                    procedure
```

Returns #t if the symbols are the same, i.e., if their names are spelled the same.

```
(string->symbol string)
                                           procedure
```

Returns the symbol whose name is *string*.

```
(eq? 'mISSISSIppi 'mississippi)

    #f
(string->symbol "mISSISSIppi")
        ⇒ the symbol with name "mISSISSIppi"
(eq? 'bitBlt (string->symbol "bitBlt"))
       (eq? 'JollyWog
    (string->symbol
     (symbol->string 'JollyWog)))

    #t
(string=? "K. Harper, M.D."
        (symbol->string
          (string->symbol "K. Harper, M.D.")))
```

11.11. Characters

Characters are objects that represent Unicode scalar values [?].

Note: Unicode defines a standard mapping between sequences of Unicode scalar values (integers in the range 0 to #x10FFFF, excluding the range #xD800 to #xDFFF) in the latest version of the standard and human-readable "characters". More precisely, Unicode distinguishes between glyphs, which are printed for humans to read, and characters, which are abstract entities that map to glyphs (sometimes in a way that's sensitive to surrounding characters). Furthermore, different sequences of scalar values sometimes correspond to the same character. The relationships among scalar, characters, and glyphs are subtle and complex.

Despite this complexity, most things that a literate human would call a "character" can be represented by a single Unicode scalar value (although several sequences of Unicode scalar values may represent that same character). For example, Roman letters, Cyrillic letters, Hebrew consonants, and most Chinese characters fall into this category.

Unicode scalar values exclude the range #xD800 to #xDFFF, which are part of the range of Unicode code points. However, the Unicode code points in this range, the so-called surrogates, are an artifact of the UTF-16 encoding, and can only appear in specific Unicode encodings, and even then only in pairs that encode scalar values. Consequently, all characters represent code points, but the surrogate code points do not have representations as characters.

```
(char? obj)
                                              procedure
```

Returns #t if *obj* is a character, otherwise returns #f.

```
(char->integer char)
                                          procedure
                                          procedure
(integer->char sv)
```

Sv must be a Unicode scalar value, i.e., a non-negative exact integer object in $[0, \#xD7FF] \cup [\#xE000, \#x10FFFF]$.

Given a character, char->integer returns its Unicode scalar value as an exact integer object. For a Unicode scalar value sv, integer->char returns its associated character.

```
(integer->char 32)
                         ⇒ #\space
(char->integer (integer->char 5000))
                         ⇒ 5000
(integer->char \#\xD800 \implies \&assertion exception
```

```
(char=? char_1 char_2 char_3 ...)
                                                      procedure
                                                      procedure
(char<? char_1 \ char_2 \ char_3 \ ...)
(char>? char_1 \ char_2 \ char_3 \ ...)
                                                      procedure
(char<=? char_1 \ char_2 \ char_3 \dots)
                                                      procedure
(char>=? char_1 \ char_2 \ char_3 \dots)
                                                      procedure
```

These procedures impose a total ordering on the set of characters according to their Unicode scalar values.

```
(char<? #\z #\ß)
(char<? #\z #\Z)

    #f
```

11.12. Strings

Strings are sequences of characters.

The *length* of a string is the number of characters that it contains. This number is fixed when the string is created. The valid indices of a string are the integers less than the length of the string. The first character of a string has index 0, the second has index 1, and so on.

```
(string? obj)
                                             procedure
```

Returns #t if obj is a string, otherwise returns #f.

```
(make-string k)
                                           procedure
                                           procedure
(make-string k char)
```

Returns a newly allocated string of length k. If char is given, then all elements of the string are initialized to *char*, otherwise the contents of the *string* are unspecified.

```
(string char ...)
                                              procedure
```

Returns a newly allocated string composed of the arguments.

```
(string-length string)
                                            procedure
```

Returns the number of characters in the given string as an exact integer object.

```
(string-ref string k)
                                             procedure
```

K must be a valid index of string. The string-ref procedure returns character k of string using zero-origin indexing.

Note: Implementors should make string-ref run in constant time.

```
(string=? string_1 \ string_2 \ string_3 \dots)
                                                        procedure
```

Returns #t if the strings are the same length and contain the same characters in the same positions. Otherwise, the string=? procedure returns #f.

```
(string=? "Straße" "Strasse")
```

```
(string<? string_1 \ string_2 \ string_3 \dots)
                                                       procedure
(string>? string_1 \ string_2 \ string_3 \dots)
                                                        procedure
(string<=? string_1 \ string_2 \ string_3 \dots)
                                                        procedure
(string>=? string_1 \ string_2 \ string_3 \dots)
                                                       procedure
```

These procedures are the lexicographic extensions to strings of the corresponding orderings on characters. For example, string<? is the lexicographic ordering on strings induced by the ordering char<? on characters. If two strings differ in length but are the same up to the length of the shorter string, the shorter string is considered to be lexicographically less than the longer string.

```
(string<? "z" "ß")
(string<? "z" "zz")
                          \implies #t
(string<? "z" "Z")
```

```
(substring string start end)
```

procedure

String must be a string, and start and end must be exact integer objects satisfying

```
0 \le start \le end \le (string-length string).
```

The substring procedure returns a newly allocated string formed from the characters of string beginning with index start (inclusive) and ending with index *end* (exclusive).

```
(string-append string ...)
                                           procedure
```

Returns a newly allocated string whose characters form the concatenation of the given strings.

```
(string->list string)
                                           procedure
(list->string list)
                                           procedure
```

List must be a list of characters. The string->list procedure returns a newly allocated list of the characters that make up the given string. The list->string procedure returns a newly allocated string formed from the characters in *list*. The string->list and list->string procedures are inverses so far as equal? is concerned.

```
(string-for-each proc\ string_1\ string_2\ \dots) procedure
```

The strings must all have the same length. Proc should accept as many arguments as there are strings. The string-foreach procedure applies proc element-wise to the characters of the *strings* for its side effects, in order from the first characters to the last. *Proc* is always called in the same dynamic environment as string-for-each itself. The return values of string-for-each are unspecified.

Analogous to for-each.

Implementation responsibilities: The implementation must check the restrictions on *proc* to the extent performed by applying it as described. An implementation may check whether *proc* is an appropriate argument before applying it.

```
(string-copy string) procedure
```

Returns a newly allocated copy of the given string.

11.13. Vectors

Vectors are heterogeneous structures whose elements are indexed by integers. A vector typically occupies less space than a list of the same length, and the average time needed to access a randomly chosen element is typically less for the vector than for the list.

The *length* of a vector is the number of elements that it contains. This number is a non-negative integer that is fixed when the vector is created. The *valid indices* of a vector are the exact non-negative integer objects less than the length of the vector. The first element in a vector is indexed by zero, and the last element is indexed by one less than the length of the vector.

Like list constants, vector constants must be quoted:

(vector? *obj*) procedure

Returns #t if obj is a vector. Otherwise the procedure returns #f.

```
(make-vector k) procedure (make-vector k fill) procedure
```

Returns a newly allocated vector of k elements. If a second argument is given, then each element is initialized to *fill*. Otherwise the initial contents of each element is unspecified.

```
(vector obj ...) procedure
```

Returns a newly allocated vector whose elements contain the given arguments. Analogous to list.

```
(vector 'a 'b 'c) \implies #(a b c)
```

(vector-length vector)
procedure

Returns the number of elements in *vector* as an exact integer object.

```
(vector-ref\ vector\ k) procedure
```

K must be a valid index of *vector*. The vector-ref procedure returns the contents of element k of *vector*.

```
(vector-ref '#(1 1 2 3 5 8 13 21) 5) \implies 8
```

```
(vector-set! vector k obj) procedure
```

K must be a valid index of *vector*. The vector-set! procedure stores *obj* in element k of *vector*, and returns unspecified values.

Passing an immutable vector to vector-set! should cause an exception with condition type &assertion to be raised.

The vector->list procedure returns a newly allocated list of the objects contained in the elements of *vector*. The list->vector procedure returns a newly created vector initialized to the elements of the list *list*.

```
(vector-fill! vector fill) procedure
```

Stores *fill* in every element of *vector* and returns unspecified values.

```
(vector-map proc\ vector_1\ vector_2\ \dots) procedure
```

The *vector*s must all have the same length. *Proc* should accept as many arguments as there are *vector*s and return a single value.

The vector-map procedure applies *proc* element-wise to the elements of the *vectors* and returns a vector of the results, in order. *Proc* is always called in the same dynamic environment as vector-map itself. The order in which *proc* is applied to the elements of the *vectors* is unspecified. If multiple returns occur from vector-map, the return values returned by earlier returns are not mutated.

Analogous to map.

Implementation responsibilities: The implementation must check the restrictions on *proc* to the extent performed by applying it as described. An implementation may check whether *proc* is an appropriate argument before applying it.

```
(vector-for-each proc\ vector_1\ vector_2\ \dots)
                                                  procedure
```

The vectors must all have the same length. Proc should accept as many arguments as there are vectors. The vector-foreach procedure applies proc element-wise to the elements of the vectors for its side effects, in order from the first elements to the last. *Proc* is always called in the same dynamic environment as vector-for-each itself. The return values of vectorfor-each are unspecified.

Analogous to for-each.

Implementation responsibilities: The implementation must check the restrictions on proc to the extent performed by applying it as described. An implementation may check whether proc is an appropriate argument before applying it.

11.14. Errors and violations

```
procedure
(error who message irritant_1 \dots)
(assertion-violation who message irritant_1 \dots)
                                               procedure
```

Who must be a string or a symbol or #f. Message must be a string. The *irritants* are arbitrary objects.

These procedures raise an exception. The error procedure should be called when an error has occurred, typically caused by something that has gone wrong in the interaction of the program with the external world or the user. The assertionviolation procedure should be called when an invalid call to a procedure was made, either passing an invalid number of arguments, or passing an argument that it is not specified to handle.

The who argument should describe the procedure or operation that detected the exception. The message argument should describe the exceptional situation. The irritants should be the arguments to the operation that detected the operation.

The condition object provided with the exception (see library chapter ??) has the following condition types:

- If who is not #f, the condition has condition type &who, with who as the value of its field. In that case, who should be the name of the procedure or entity that detected the exception. If it is #f, the condition does not have condition type &who.
- The condition has condition type &message, with message as the value of its field.
- The condition has condition type &irritants, and its field has as its value a list of the *irritants*.

Moreover, the condition created by error has condition type &error, and the condition created by assertionviolation has condition type &assertion.

```
(define (fac n)
 (if (not (integer-valued? n))
     (assertion-violation
      'fac "non-integral argument" n))
 (if (negative? n)
     (assertion-violation
      'fac "negative argument" n))
 (let.rec
   ((loop (lambda (n r)
           (if (zero? n)
               (loop (-n 1) (*rn)))))
     (loop n 1)))
(fac 5)
                        ⇒ 120
(fac 4.5)
                       ⇒ &assertion exception
(fac -3)
                       \implies &assertion exception
```

```
(assert ⟨expression⟩)
                                                  syntax
```

An assert form is evaluated by evaluating (expression). If (expression) returns a true value, that value is returned from the assert expression. If ⟨expression⟩ returns #f, an exception with condition types &assertion and &message is raised. The message provided in the condition object is implementationdependent.

Note: Implementations should exploit the fact that assert is syntax to provide as much information as possible about the location of the assertion failure.

11.15. Control features

This chapter describes various primitive procedures which control the flow of program execution in special ways.

```
(apply proc arg_1 \dots rest-args)
                                                  procedure
```

Rest-args must be a list. Proc should accept n arguments, where n is number of args plus the length of rest-args. The apply procedure calls proc with the elements of the list (append (list arg_1 ...) rest-args) as the actual arguments.

If a call to apply occurs in a tail context, the call to proc is also in a tail context.

```
(apply + (list 3 4))
(define compose
  (lambda (f g)
    (lambda args
      (f (apply g args)))))
((compose sqrt *) 12 75) \Longrightarrow 30
```

```
(call-with-current-continuation proc)
                                       procedure
```

```
(call/cc proc)
                                            procedure
```

Proc should accept one argument. The procedure callwith-current-continuation (which is the same as the procedure call/cc) packages the current continuation as an "escape procedure" and passes it as an argument to proc. The escape procedure is a Scheme procedure that, if it is later called, will abandon whatever continuation is in effect at that later time and will instead reinstate the continuation that was in effect when the escape procedure was created. Calling the escape procedure may cause the invocation of before and after procedures installed using dynamic-wind.

The escape procedure accepts the same number of arguments as the continuation of the original call to call-withcurrent-continuation.

The escape procedure that is passed to proc has unlimited extent just like any other procedure in Scheme. It may be stored in variables or data structures and may be called as many times as desired.

If a call to call-with-current-continuation occurs in a tail context, the call to proc is also in a tail context.

The following examples show only some ways in which callwith-current-continuation is used. If all real uses were as simple as these examples, there would be no need for a procedure with the power of call-with-currentcontinuation.

```
(call-with-current-continuation
  (lambda (exit)
   (for-each (lambda (x)
              (if (negative? x)
                  (exit x)))
            '(54 0 37 -3 245 19))
   #t))
(define list-length
 (lambda (obj)
   (call-with-current-continuation
     (lambda (return)
       (letrec ((r
                (lambda (obj)
                  (cond ((null? obj) 0)
                        ((pair? obj)
                         (+ (r (cdr obj)) 1))
                        (else (return #f))))))
         (r obj))))))
(list-length '(1 2 3 4)) \Longrightarrow 4
(list-length '(a b . c)) \Longrightarrow #f
(call-with-current-continuation procedure?)
```

Note: Calling an escape procedure reenters the dynamic extent of the call to call-with-current-continuation, and thus restores its dynamic environment; see section 5.12.

```
(values obj \dots)
                                                  procedure
```

Delivers all of its arguments to its continuation. The values procedure might be defined as follows:

```
(define (values . things)
 (call-with-current-continuation
   (lambda (cont) (apply cont things))))
```

The continuations of all non-final expressions within a sequence of expressions, such as in lambda, begin, let, let*, letrec, letrec*, let-values, let*-values, case, and cond forms, usually take an arbitrary number of values.

Except for these and the continuations created by call-withvalues, let-values, and let*-values, continuations implicitly accepting a single value, such as the continuations of (operator) and (operand)s of procedure calls or the (test) expressions in conditionals, take exactly one value. The effect of passing an inappropriate number of values to such a continuation is undefined.

```
(call-with-values producer consumer)
                                          procedure
```

Producer must be a procedure and should accept zero arguments. Consumer must be a procedure and should accept as many values as *producer* returns. The call-with-values procedure calls *producer* with no arguments and a continuation that, when passed some values, calls the *consumer* procedure with those values as arguments. The continuation for the call to *consumer* is the continuation of the call to call-with-values.

```
(call-with-values (lambda () (values 4 5))
                 (lambda (a b) b))
                          \implies 5
(call-with-values * -) \implies -1
```

If a call to call-with-values occurs in a tail context, the call to *consumer* is also in a tail context.

Implementation responsibilities: After producer returns, the implementation must check that consumer accepts as many values as *consumer* has returned.

```
(dynamic-wind before thunk after)
                                            procedure
```

Before, thunk, and after must be procedures, and each should accept zero arguments. These procedures may return any number of values. The dynamic-wind procedure calls thunk without arguments, returning the results of this call. Moreover, dynamic-wind calls before without arguments whenever the dynamic extent of the call to thunk is entered, and after without arguments whenever the dynamic extent of the call to thunk is exited. Thus, in the absence of calls to escape procedures created by call-with-current-continuation, dynamicwind calls before, thunk, and after, in that order.

While the calls to before and after are not considered to be within the dynamic extent of the call to thunk, calls to the before and after procedures of any other calls to dynamic-wind that occur within the dynamic extent of the call to thunk are considered to be within the dynamic extent of the call to thunk.

More precisely, an escape procedure transfers control out of the dynamic extent of a set of zero or more active dynamicwind calls x ... and transfer control into the dynamic extent of a set of zero or more active dynamic-wind calls y It leaves the dynamic extent of the most recent x and calls without arguments the corresponding after procedure. If the after procedure returns, the escape procedure proceeds to the next most recent x, and so on. Once each x has been handled in this manner, the escape procedure calls without arguments the before procedure corresponding to the least recent y. If the before procedure returns, the escape procedure reenters the dynamic extent of the least recent y and proceeds with the next least recent y, and so on. Once each y has been handled in this manner, control is transferred to the continuation packaged in the escape procedure.

Implementation responsibilities: The implementation must check the restrictions on thunk and after only if they are actually called.

```
(let ((path '())
     (c #f))
 (let ((add (lambda (s)
             (set! path (cons s path)))))
   (dynamic-wind
     (lambda () (add 'connect))
     (lambda ()
       (add (call-with-current-continuation
             (lambda (c0)
               (set! c c0)
               'talk1))))
     (lambda () (add 'disconnect)))
   (if (< (length path) 4)
       (c 'talk2)
       (reverse path))))
        ⇒ (connect talk1 disconnect
             connect talk2 disconnect)
(let ((n 0))
 (call-with-current-continuation
   (lambda (k)
     (dynamic-wind
       (lambda ()
         (set! n (+ n 1))
         (k))
       (lambda ()
         (set! n (+ n 2)))
       (lambda ()
         (set! n (+ n 4))))))
 n)
                        \implies 1
(let ((n 0))
 (call-with-current-continuation
   (lambda (k)
     (dynamic-wind
      values
       (lambda ()
         (dynamic-wind
          values
          (lambda ()
            (set! n (+ n 1))
           (lambda ()
            (set! n (+ n 2))
            (k))))
       (lambda ()
         (set! n (+ n 4))))))
 n)
                         \implies 7
```

Note: Entering a dynamic extent restores its dynamic environment; see section 5.12.

11.16. Iteration

```
(let \langle variable \rangle \langle bindings \rangle \langle body \rangle)
                                                                                                        syntax
```

"Named let" is a variant on the syntax of let that provides a general looping construct and may also be used to express recursion. It has the same syntax and semantics as ordinary let except that (variable) is bound within (body) to a procedure whose parameters are the bound variables and whose body is $\langle body \rangle$. Thus the execution of $\langle body \rangle$ may be repeated by invoking the procedure named by (variable).

```
(let loop ((numbers '(3 -2 1 6 -5))
         (nonneg '())
         (neg '()))
 (cond ((null? numbers) (list nonneg neg))
       ((>= (car numbers) 0)
       (loop (cdr numbers)
             (cons (car numbers) nonneg)
             nea))
       ((< (car numbers) 0)
        (loop (cdr numbers)
            nonneg
             (cons (car numbers) neg()))))
        \implies ((6 1 3) (-5 -2))
```

11.17. Quasiquotation

```
(quasiquote \langle qq \ template \rangle)
                                                        svntax
unquote
                                               auxiliary syntax
unquote-splicing
                                              auxiliary syntax
```

"Backguote" or "quasiquote" expressions are useful for constructing a list or vector structure when some but not all of the desired structure is known in advance.

Syntax: (Qq template) should be as specified by the grammar at the end of this entry.

Semantics: If no unquote or unquote-splicing forms appear within the \(\langle qq\) template\(\rangle \), the result of evaluating (quasiquote (qq template)) is equivalent to the result of evaluating (quote (qq template)).

If an (unquote (expression) ...) form appears inside a (qq template), however, the (expression)s are evaluated ("unquoted") and their results are inserted into the structure instead of the unquote form.

If an (unquote-splicing (expression) ...) form appears inside a $\langle qq \text{ template} \rangle$, then the $\langle expression \rangle$ s must evaluate to lists; the opening and closing parentheses of the lists are then "stripped away" and the elements of the lists are inserted in place of the unquote-splicing form.

Any unquote-splicing or multi-operand unquote form must appear only within a list or vector (qq template).

As noted in section 4.3.5, (quasiquote $\langle qq \text{ template} \rangle$) may be abbreviated $\Box \langle qq \text{ template} \rangle$, (unquote $\langle expression \rangle$) may be abbreviated , $\langle expression \rangle$, and (unquote-splicing $\langle expression \rangle$) may be abbreviated , $\emptyset \langle expression \rangle$.

```
\Box (list , (+ 1 2) 4)
                            \implies (list 3 4)
(let ((name 'a)) □(list ,name ',name))
         \implies (list a (quote a))
\square (a , (+ 1 2) ,@(map abs ' (4 -5 6)) b)
         \implies (a 3 4 5 6 b)
\square (( foo , (- 10 3)) ,@(cdr '(c)) . ,(car '(cons)))
          \implies ((foo 7) . cons)
\square#(10 5 ,(sqrt 4) ,@(map sqrt '(16 9)) 8)
          \implies # (10 5 2 4 3 8)
(let ((name 'foo))
 ☐ ((unquote name name name)))
         \implies (foo foo foo)
(let ((name '(foo)))
 ☐((unquote-splicing name name name)))
         \implies (foo foo foo)
(let ((q '((append x y) (sqrt 9))))
 □□(foo "@q))
          \Longrightarrow \Box (foo
                 (unquote (append x y) (sqrt 9)))
(let ((x '(2 3))
      (y '(4 5)))
 \square (foo (unquote (append x y) (sqrt 9))))
          \implies (foo (2 3 4 5) 3)
```

Quasiquote forms may be nested. Substitutions are made only for unquoted components appearing at the same nesting level as the outermost quasiquote. The nesting level increases by one inside each successive quasiquotation, and decreases by one inside each unquotation.

A quasiquote expression may return either fresh, mutable objects or literal structure for any structure that is constructed at run time during the evaluation of the expression. Portions that do not need to be rebuilt are always literal. Thus,

```
(let ((a 3)) \square ((1 2), a, 4, 'five 6))
```

may be equivalent to either of the following expressions:

However, it is not equivalent to this expression:

```
(let ((a 3)) (list (list 1 2) a 4 'five 6))
```

It is a syntax violation if any of the identifiers quasiquote, unquote, or unquote-splicing appear in positions within a $\langle qq \text{ template} \rangle$ otherwise than as described above.

The following grammar for quasiquote expressions is not context-free. It is presented as a recipe for generating an infinite number of production rules. Imagine a copy of the following rules for $D=1,2,3,\ldots D$ keeps track of the nesting depth.

```
\langle qq \text{ template} \rangle \longrightarrow \langle qq \text{ template } 1 \rangle
\langle qq \text{ template } 0 \rangle \longrightarrow \langle expression \rangle
\langle \text{quasiquotation } D \rangle \longrightarrow (\text{quasiquote } \langle \text{qq template } D \rangle)
\langle qq \text{ template } D \rangle \longrightarrow \langle lexeme \text{ datum} \rangle
             \langle \text{list qq template } D \rangle
             \langle \text{vector qq template } D \rangle
             \langle \text{unquotation } D \rangle
\langle \text{list qq template } D \rangle \longrightarrow (\langle \text{qq template or splice } D \rangle^*)
              (\langle qq \text{ template or splice } D \rangle^+ \cdot \langle qq \text{ template } D \rangle)
             \langle \text{quasiquotation } D + 1 \rangle
\langle \text{vector qq template } D \rangle \longrightarrow \# (\langle \text{qq template or splice } D \rangle^*)
\langle \text{unquotation } D \rangle \longrightarrow (\text{unquote } \langle \text{qq template } D - 1 \rangle)
\langle qq \text{ template or splice } D \rangle \longrightarrow \langle qq \text{ template } D \rangle
          |\langle \text{splicing unquotation } D \rangle|
\langle \text{splicing unquotation } D \rangle \longrightarrow
              (unquote-splicing \langle qq \text{ template } D-1 \rangle^*)
         (unquote \langle qq \text{ template } D-1 \rangle^*)
```

In $\langle \text{quasiquotation} \rangle s$, a $\langle \text{list qq template } D \rangle$ can sometimes be confused with either an $\langle \text{unquotation } D \rangle$ or a $\langle \text{splicing unquotation } D \rangle$. The interpretation as an $\langle \text{unquotation} \rangle$ or $\langle \text{splicing unquotation } D \rangle$ takes precedence.

11.18. Binding constructs for syntactic keywords

The let-syntax and letrec-syntax forms bind keywords. Like a begin form, a let-syntax or letrec-syntax form may appear in a definition context, in which case it is treated as a definition, and the forms in the body must also be definitions. A let-syntax or letrec-syntax form may also appear in an expression context, in which case the forms within their bodies must be expressions.

```
(let-syntax \langle bindings \rangle \langle form \rangle \dots) syntax Syntax: \langle Bindings \rangle must have the form ((\langle keyword \rangle \langle expression \rangle) \dots)
```

Each \(\)keyword\\ is an identifier, and each \(\)expression\\ is an expression that evaluates, at macro-expansion time, to a \(transformer \). Transformers may be created by \(\)syntax-rules or identifier-\(\)syntax (see section 11.19) or by one of the other mechanisms described in library chapter ??. It is a syntax violation for \(\)keyword\\ to appear more than once in the list of keywords being bound.

Semantics: The \(\)form\\s are expanded in the syntactic environment obtained by extending the syntactic environment of the let-syntax form with macros whose keywords are the \(\)keyword\\s, bound to the specified transformers. Each binding of a \(\)keyword\\ has the \(\)form\\s as its region.

The $\langle \text{form} \rangle \text{s}$ of a let-syntax form are treated, whether in definition or expression context, as if wrapped in an implicit begin; see section 11.4.7. Thus definitions in the result of expanding the $\langle \text{form} \rangle \text{s}$ have the same region as any definition appearing in place of the let-syntax form would have.

Implementation responsibilities: The implementation should detect if the value of $\langle expression \rangle$ cannot possibly be a transformer.

```
(let-syntax ((when (syntax-rules ()
                   ((when test stmt1 stmt2 ...) letrec-syntax differ.
                    (if test
                       (begin stmt1
                             stmt2 ...))))))
 (let ((if #t))
   (when if (set! if 'now))
   if))
                         \implies now
(let ((x 'outer))
 (let-syntax ((m (syntax-rules () ((m) x))))
   (let ((x 'inner))
     (m))))
                            outer
(let ()
 (let-syntax
   ((def (syntax-rules ()
          ((def stuff ...) (define stuff ...))))
   (def foo 42))

⇒ 42

 foo)
(let ()
 (let-syntax ())
 5)
                         \implies 5
```

(letrec-syntax $\langle bindings \rangle \langle form \rangle \dots$) syntax

Syntax: Same as for let-syntax.

Semantics: The \(\)form\\\ s \\ are \(\)expanded in the syntactic environment obtained by extending the syntactic environment of the letrec-syntax form with macros whose keywords are the (keyword)s, bound to the specified transformers. Each binding of a \(\lambda\) keyword\\\ has the \(\lambda\) bindings\\\ as well as the \(\lambda\) form\\\ s within its region, so the transformers can transcribe forms into uses of the macros introduced by the letrec-syntax form.

The $\langle form \rangle s$ of a letrec-syntax form are treated, whether in definition or expression context, as if wrapped in an implicit begin; see section 11.4.7. Thus definitions in the result of expanding the (form)s have the same region as any definition appearing in place of the letrec-syntax form would have.

Implementation responsibilities: The implementation should detect if the value of (expression) cannot possibly be a transformer.

```
(letrec-syntax
 ((my-or (syntax-rules ()
           ((my-or) #f)
           ((my-or e) e)
           ((my-or e1 e2 ...)
            (let ((temp e1))
              (if temp
                 (my-or e2 ...))))))
  (let ((x #f)
       (y 7)
       (temp 8)
       (let odd?)
       (if even?))
   (my-or x
          (let temp)
          (if y)
          y)))
                         \implies 7
```

The following example highlights how let-syntax and

```
(let ((f (lambda (x) (+ x 1))))
  (let-syntax ((f (syntax-rules ()
                  ((f x) x)))
             (g (syntax-rules ()
                  ((g x) (f x))))
   (list (f 1) (q 1)))
        \implies (1 2)
(let ((f (lambda (x) (+ x 1))))
 (letrec-syntax ((f (syntax-rules ()
                     ((f x) x))
                (g (syntax-rules ()
                     ((g x) (f x))))
   (list (f 1) (g 1))))
        \implies (1 1)
```

The two expressions are identical except that the let-syntax form in the first expression is a letrec-syntax form in the second. In the first expression, the f occurring in g refers to the let-bound variable f, whereas in the second it refers to the keyword f whose binding is established by the letrecsyntax form.

11.19. Macro transformers

```
(syntax-rules (\langle literal \rangle \dots) \langle syntax rule \rangle \dots)
                                                   syntax (expand)
                                       auxiliary syntax (expand)
                                       auxiliary syntax (expand)
```

Syntax: Each (literal) must be an identifier. Each (syntax rule) must have the following form:

```
((srpattern) (template))
```

An (srpattern) is a restricted form of (pattern), namely, a nonempty (pattern) in one of four parenthesized forms below whose first subform is an identifier or an underscore . A (pattern) is an identifier, constant, or one of the following.

```
((pattern) ...)
(\(\bar{pattern}\)\)\ \(\langle \text{pattern}\)\ \...\ \(\langle \text{pattern}\)\)
(\langle pattern \rangle ... \langle pattern \rangle \langle ellipsis \rangle \langle pattern \rangle ...)
(\langle pattern \rangle ... \langle pattern \rangle ... \langle pattern \rangle ... \langle pattern \rangle )
# (\(\langle \text{pattern}\rangle \...\)
# (\langle pattern \rangle ... \langle pattern \rangle \langle ellipsis \rangle \langle pattern \rangle ...)
```

An (ellipsis) is the identifier "..." (three periods).

A (template) is a pattern variable, an identifier that is not a pattern variable, a pattern datum, or one of the following.

```
(\langle subtemplate \rangle ...)
((subtemplate) ... \(\text{template}\))
# (\langle subtemplate \rangle ...)
```

A $\langle \text{subtemplate} \rangle$ is a $\langle \text{template} \rangle$ followed by zero or more ellipses.

Semantics: An instance of syntax-rules evaluates, at macro-expansion time, to a new macro transformer by specifying a sequence of hygienic rewrite rules. A use of a macro whose keyword is associated with a transformer specified by syntax-rules is matched against the patterns contained in the (syntax rule)s, beginning with the leftmost (syntax rule). When a match is found, the macro use is transcribed hygienically according to the template. It is a syntax violation when no match is found.

An identifier appearing within a ⟨pattern⟩ may be an underscore (__), a literal identifier listed in the list of literals (⟨literal⟩ ...), or an ellipsis (...). All other identifiers appearing within a ⟨pattern⟩ are *pattern variables*. It is a syntax violation if an ellipsis or underscore appears in (⟨literal⟩ ...).

While the first subform of (srpattern) may be an identifier, the identifier is not involved in the matching and is not considered a pattern variable or literal identifier.

Pattern variables match arbitrary input subforms and are used to refer to elements of the input. It is a syntax violation if the same pattern variable appears more than once in a \(pattern \).

Underscores also match arbitrary input subforms but are not pattern variables and so cannot be used to refer to those elements. Multiple underscores may appear in a \(\text{pattern} \).

A literal identifier matches an input subform if and only if the input subform is an identifier and either both its occurrence in the input expression and its occurrence in the list of literals have the same lexical binding, or the two identifiers have the same name and both have no lexical binding.

A subpattern followed by an ellipsis can match zero or more elements of the input.

More formally, an input form F matches a pattern P if and only if one of the following holds:

- P is an underscore ().
- P is a pattern variable.
- P is a literal identifier and F is an identifier such that both
 P and F would refer to the same binding if both were to
 appear in the output of the macro outside of any bindings
 inserted into the output of the macro. (If neither of two
 like-named identifiers refers to any binding, i.e., both are
 undefined, they are considered to refer to the same binding.)
- P is of the form $(P_1 \ldots P_n)$ and F is a list of n elements that match P_1 through P_n .
- P is of the form $(P_1 \ldots P_n \cdot P_x)$ and F is a list or improper list of n or more elements whose first n elements match P_1 through P_n and whose nth cdr matches P_x .
- P is of the form $(P_1 \ldots P_k \ P_e \ \langle \text{ellipsis} \rangle \ P_{m+1} \ldots P_n)$, where $\langle \text{ellipsis} \rangle$ is the identifier \ldots and F is a list of n elements whose first k elements match P_1 through P_k , whose next m-k elements each match P_e , and whose remaining n-m elements match P_{m+1} through P_n .

- P is of the form $(P_1 \ldots P_k \ P_e \ \langle \text{ellipsis} \rangle \ P_{m+1} \ldots P_n \ .$ $P_x)$, where $\langle \text{ellipsis} \rangle$ is the identifier . . . and F is a list or improper list of n elements whose first k elements match P_1 through P_k , whose next m-k elements each match P_e , whose next n-m elements match P_{m+1} through P_n , and whose nth and final cdr matches P_x .
- P is of the form $\# (P_1 \ldots P_n)$ and F is a vector of n elements that match P_1 through P_n .
- P is of the form # (P_1 ... P_k P_e \langle ellipsis \rangle P_{m+1} ... P_n), where \langle ellipsis \rangle is the identifier ... and F is a vector of n or more elements whose first k elements match P_1 through P_k , whose next m-k elements each match P_e , and whose remaining n-m elements match P_{m+1} through P_m
- P is a pattern datum (any nonlist, nonvector, nonsymbol datum) and F is equal to P in the sense of the equal? procedure.

When a macro use is transcribed according to the template of the matching (syntax rule), pattern variables that occur in the template are replaced by the subforms they match in the input.

Pattern data and identifiers that are not pattern variables or ellipses are copied into the output. A subtemplate followed by an ellipsis expands into zero or more occurrences of the subtemplate. Pattern variables that occur in subpatterns followed by one or more ellipses may occur only in subtemplates that are followed by (at least) as many ellipses. These pattern variables are replaced in the output by the input subforms to which they are bound, distributed as specified. If a pattern variable is followed by more ellipses in the subtemplate than in the associated subpattern, the input form is replicated as necessary. The subtemplate must contain at least one pattern variable from a subpattern followed by an ellipsis, and for at least one such pattern variable, the subtemplate must be followed by exactly as many ellipses as the subpattern in which the pattern variable appears. (Otherwise, the expander would not be able to determine how many times the subform should be repeated in the output.) It is a syntax violation if the constraints of this paragraph are not met.

A template of the form ($\langle ellipsis \rangle$ $\langle template \rangle$) is identical to $\langle template \rangle$, except that ellipses within the template have no special meaning. That is, any ellipses contained within $\langle template \rangle$ are treated as ordinary identifiers. In particular, the template (...) produces a single ellipsis, This allows syntactic abstractions to expand into forms containing ellipses.

As an example for hygienic use of auxiliary identifier, if let and cond are defined as in section 11.4.6 and appendix B then they are hygienic (as required) and the following is not an error.

```
(let ((=> #f))
  (cond (#t => 'ok)))
                            \implies ok
```

The macro transformer for cond recognizes => as a local variable, and hence an expression, and not as the identifier =>, which the macro transformer treats as a syntactic keyword. Thus the example expands into

```
(let ((=> #f))
 (if #t (begin => 'ok)))
```

instead of

```
(let ((=> #f))
 (let ((temp #t))
   (if temp ('ok temp))))
```

which would result in an assertion violation.

```
(identifier-syntax ⟨template⟩)
                                                         syntax (expand)
(identifier-syntax
                                                         syntax (expand)
   (\langle id_1 \rangle \langle template_1 \rangle)
   ((set! \langle id_2 \rangle \langle pattern \rangle)
    \langle \text{template}_2 \rangle))
set!
                                            auxiliary syntax (expand)
```

Syntax: The (id)s must be identifiers. The (template)s must be as for syntax-rules.

Semantics: When a keyword is bound to a transformer produced by the first form of identifier-syntax, references to the keyword within the scope of the binding are replaced by ⟨template⟩.

```
(define p (cons 4 5))
(define-syntax p.car (identifier-syntax (car p)))
p.car
                         \implies 4
(set! p.car 15)
                         ⇒ &syntax exception
```

The second, more general, form of identifier-syntax permits the transformer to determine what happens when set! is used. In this case, uses of the identifier by itself are replaced by $\langle template_1 \rangle$, and uses of set! with the identifier are replaced by $\langle template_2 \rangle$.

```
(define p (cons 4 5))
(define-syntax p.car
  (identifier-syntax
    (_ (car p))
((set! _ e) (set-car! p e))))
(set! p.car 15)
p.car
                             \implies 15
                             \implies (15 5)
р
```

11.20. Tail calls and tail contexts

A tail call is a procedure call that occurs in a tail context. Tail contexts are defined inductively. Note that a tail context is always determined with respect to a particular lambda expression.

• The last expression within the body of a lambda expression, shown as \(\tail\) expression\(\text{ below, occurs in a tail context.}\)

```
(lambda (formals)
  ⟨definition⟩*
  ⟨expression⟩* ⟨tail expression⟩)
```

• If one of the following expressions is in a tail context, then the subexpressions shown as \(\tail\) expression\(\righta\) are in a tail context. These were derived from specifications of the syntax of the forms described in this chapter by replacing some occurrences of (expression) with (tail expression). Only those rules that contain tail contexts are shown here.

```
(if (expression) (tail expression))
     (if ⟨expression⟩ ⟨tail expression⟩)
     (cond \langle cond clause \rangle^+)
     (cond (cond clause)* (else (tail sequence)))
     (case (expression)
        \langle case clause \rangle^+
     (case (expression)
        ⟨case clause⟩*
        (else (tail sequence)))
     (and \(\langle\) expression\(\rangle\)* \(\langle\) tail expression\(\rangle\))
     (or ⟨expression⟩* ⟨tail expression⟩)
     (let (variable) (bindings) (tail body))
     (let * ⟨bindings⟩ ⟨tail body⟩)
     (letrec* ⟨bindings⟩ ⟨tail body⟩)
     (letrec (bindings) (tail body))
     (let-values ⟨mv-bindings⟩ ⟨tail body⟩)
     (let*-values ⟨mv-bindings⟩ ⟨tail body⟩)
     (let-syntax (bindings) (tail body))
     (letrec-syntax (bindings) (tail body))
     (begin (tail sequence))
A (cond clause) is
     (\langle test \rangle \tail sequence \rangle),
a (case clause) is
     ((\langle datum \rangle^*) \langle tail sequence \rangle),
a (tail body) is
     ⟨definition⟩* ⟨tail sequence⟩,
```

```
and a \(\tail\) sequence\(\) is
     ⟨expression⟩* ⟨tail expression⟩.
```

• If a cond expression is in a tail context, and has a clause of the form $(\langle expression_1 \rangle => \langle expression_2 \rangle)$ then the (implied) call to the procedure that results from the evaluation of $\langle expression_2 \rangle$ is in a tail context. $\langle Expression_2 \rangle$ itself is not in a tail context.

Certain built-in procedures must also perform tail calls. The first argument passed to apply and to call-with-currentcontinuation, and the second argument passed to callwith-values, must be called via a tail call.

In the following example the only tail call is the call to f. None of the calls to g or h are tail calls. The reference to x is in a tail context, but it is not a call and thus is not a tail call.

```
(lambda ()
 (if (g)
     (let ((x (h)))
     (and (g) (f))))
```

Note: Implementations may recognize that some non-tail calls, such as the call to h above, can be evaluated as though they were tail calls. In the example above, the let expression could be compiled as a tail call to h. (The possibility of h returning an unexpected number of values can be ignored, because in that case the effect of the let is explicitly unspecified and implementation-dependent.)

APPENDICES

Приложение А. Formal semantics

This appendix presents a non-normative, formal, operational semantics for Scheme, that is based on an earlier semantics [?]. It does not cover the entire language. The notable missing features are the macro system, I/O, and the numerical tower. The precise list of features included is given in section A.2.

The core of the specification is a single-step term rewriting relation that indicates how an (abstract) machine behaves. In general, the report is not a complete specification, giving implementations freedom to behave differently, typically to allow optimizations. This underspecification shows up in two ways in the semantics.

The first is reduction rules that reduce to special "unknown: string" states (where the string provides a description of the unknown state). The intention is that rules that reduce to such states can be replaced with arbitrary reduction rules. The precise specification of how to replace those rules is given in section A.12.

The other is that the single-step relation relates one program to multiple different programs, each corresponding to a legal transition that an abstract machine might take. Accordingly we use the transitive closure of the single step relation \rightarrow^* to define the semantics, S, as a function from programs (P) to sets of observable results (\mathcal{R}):

$$\begin{array}{l} \mathcal{S}: \mathcal{P} \longrightarrow 2^{\mathcal{R}} \\ \mathcal{S}(\mathcal{P}) = \{ \mathscr{O}(\mathcal{A}) \mid \mathcal{P} \rightarrow^* \mathcal{A} \} \end{array}$$

where the function \mathcal{O} turns an answer (\mathcal{A}) from the semantics into an observable result. Roughly, \mathcal{O} is the identity function on simple base values, and returns a special tag for more complex values, like procedure and pairs.

So, an implementation conforms to the semantics if, for every program \mathcal{P} , the implementation produces one of the results in $\mathcal{S}(\mathcal{P})$ or, if the implementation loops forever, then there is an infinite reduction sequence starting at \mathcal{P} , assuming that the reduction relation \rightarrow has been adjusted to replace the **unknown**: states.

The precise definitions of \mathcal{P} , \mathcal{A} , \mathcal{R} , and \mathcal{O} are also given in section A.2.

To help understand the semantics and how it behaves, we have implemented it in PLT Redex. The implementation is available at the report's website: http://www.r6rs.org/. All of the reduction rules and the metafunctions shown in the figures in this semantics were generated automatically from the source code.

A.1. Background

We assume the reader has a basic familiarity with contextsensitive reduction semantics. Readers unfamiliar with this system may wish to consult Felleisen and Flatt's monograph [?] or Wright and Felleisen [?] for a thorough introduction, including the relevant technical background, or an introduction to PLT Redex [?] for a somewhat lighter one.

As a rough guide, we define the operational semantics of a language via a relation on program terms, where the relation corresponds to a single step of an abstract machine. The relation is defined using evaluation contexts, namely terms with a distinguished place in them, called holes, where the next step of evaluation occurs. We say that a term e decomposes into an evaluation context E and another term e' if e is the same as Ebut with the hole replaced by e'. We write E[e'] to indicate the term obtained by replacing the hole in E with e'.

For example, assuming that we have defined a grammar containing non-terminals for evaluation contexts (E), expressions (e), variables (x), and values (v), we would write:

$$\begin{array}{l} E_1\big[\,\text{((lambda }(x_1\cdots)\ e_1)\ v_1\cdots)\,\big]\to\\ E_1\big[\{x_1\cdots\mapsto v_1\cdots\}e_1\big]\quad (\#x_1=\#v_1) \end{array}$$

to define the β_v rewriting rule (as a part of the \rightarrow single step relation). We use the names of the non-terminals (possibly with subscripts) in a rewriting rule to restrict the application of the rule, so it applies only when some term produced by that grammar appears in the corresponding position in the term. If the same non-terminal with an identical subscript appears multiple times, the rule only applies when the corresponding terms are structurally identical (nonterminals without subscripts are not constrained to match each other). Thus, the occurrence of E_1 on both the left-hand and right-hand side of the rule above means that the context of the application expression does not change when using this rule. The ellipses are a form of Kleene star, meaning that zero or more occurrences of terms matching the pattern proceeding the ellipsis may appear in place of the the ellipsis and the pattern preceding it. We use the notation $\{x_1 \cdots \mapsto v_1 \cdots\}e_1$ for capture-avoiding substitution; in this case it means that each x_1 is replaced with the corresponding v_1 in e_1 . Finally, we write side-conditions in parentheses beside a rule; the side-condition in the above rule indicates that the number of x_1 s must be the same as the number of v_1 s. Sometimes we use equality in the side-conditions: when we do it merely means simple term equality, i.e., the two terms must have the same syntactic shape.

Making the evaluation context E explicit in the rule allows us to define relations that manipulate their context. As a simple example, we can add another rule that signals a violation when a procedure is applied to the wrong number of arguments by discarding the evaluation context on the right-hand side of a rule:

Later we take advantage of the explicit evaluation context in more sophisticated ways.

A.2. Grammar

Figure A.2a shows the grammar for the subset of the report this semantics models. Non-terminals are written in italics or in a

Рис. A.2b: Grammar for evaluation contexts

calligraphic font $(\mathcal{P} \mathcal{A}, \mathcal{R}, \text{ and } \mathcal{R}_v)$ and literals are written in a monospaced font.

The \mathcal{P} non-terminal represents possible program states. The first alternative is a program with a store and an expression. The second alternative is an uncaught exception, and the third is used to indicate a place where the model does not completely specify the behavior of the primitives it models (see section A.12 for details of those situations). The A non-terminal represents a final result of a program. It is just like \mathcal{P} except that expression has been reduced to some sequence of values.

The \mathcal{R} and \mathcal{R}_v non-terminals specify the observable results of a program. Each R is either a sequence of values that correspond to the values produced by the program that terminates normally, or a tag indicating an uncaught exception was raised, or unknown if the program encounters a situation the semantics does not cover. The \mathcal{R}_v non-terminal specifies what the observable results are for a particular value: a pair, the empty list, a symbol, a self-quoting value (#t, #f, and numbers), a condition, or a procedure.

The sf non-terminal generates individual elements of the store. The store holds all of the mutable state of a program. It is explained in more detail along with the rules that manipulate it.

Expressions (es) include quoted data, begin expressions, begin0 expressions¹, application expressions, if expressions, set! expressions, variables, non-procedure values (nonproc), primitive procedures (pproc), lambda expressions, letrec and letrec* expressions.

The last few expression forms are only generated for intermediate states (dw for dynamic-wind, throw for continuations, unspecified for the result of the assignment operators, handlers for exception handlers, and 1! and reinit for letrec), and should not appear in an initial program. Their use is described in the relevant sections of this appendix.

The f non-terminal describes the formals for lambda expressions. (The dot is used instead of a period for procedures that accept an arbitrary number of arguments, in order to avoid meta-circular confusion in our PLT Redex model.)

```
(call-with-values
                            (lambda () e_1)
(begin0 e_1 e_2 \cdots) =
                            (lambda x)
                             (apply values x)))
```

The s non-terminal covers all datums, which can be either non-empty sequences (seq), the empty sequence, self-quoting values (sqv), or symbols. Non-empty sequences are either just a sequence of datums, or they are terminated with a dot followed by either a symbol or a self-quoting value. Finally the selfquoting values are numbers and the booleans #t and #f.

The p non-terminal represents programs that have no quoted data. Most of the reduction rules rewrite p to p, rather than \mathcal{P} to \mathcal{P} , since quoted data is first rewritten into calls to the list construction functions before ordinary evaluation proceeds. In parallel to es, e represents expressions that have no quoted expressions.

The values (v) are divided into four categories:

- Non-procedures (nonproc) include pair pointers (pp), the empty list (null), symbols, self-quoting values (sqv), and conditions. Conditions represent the report's condition values, but here just contain a message and are otherwise inert.
- User procedures ((lambda $f e e \cdots$)) include multi-arity lambda expressions and lambda expressions with dotted parameter lists,
- Primitive procedures (pproc) include
 - arithmetic procedures (aproc): +, -, /, and *,
 - procedures of one argument (proc1): null?, pair?, car, cdr, call/cc, procedure?, condition?, unspecified?, raise, and raise-continuable.
 - procedures of two arguments (proc2): cons, set-car!, set-cdr!, eqv?, and call-withvalues,
 - as well as list, dynamic-wind, apply, values, and with-exception-handler.
- Finally, continuations are represented as throw expressions whose body consists of the context where the continuation was grabbed.

The next three set of non-terminals in figure A.2a represent pairs (pp), which are divided into immutable pairs (ip) and mutable pairs (mp). The final set of non-terminals in figure A.2a, sym, x, and n represent symbols, variables, and numbers respectively. The non-terminals ip, mp, and sym are all assumed to all be disjoint. Additionally, the variables x are assumed not to include any keywords or primitive operations, so any program variables whose names coincide with them must be renamed before the semantics can give the meaning of that program.

¹ begin0 is not part of the standard, but we include it to make the rules for dynamic-wind and letrec easier to read. Although we model it directly, it can be defined in terms of other forms we model here that do come from the standard:

Рис. A.4: Multiple values and call-with-values

The set of non-terminals for evaluation contexts is shown in figure A.2b. The P non-terminal controls where evaluation happens in a program that does not contain any quoted data. The E and F evaluation contexts are for expressions. They are factored in that manner so that the PG, G, and H evaluation contexts can re-use F and have fine-grained control over the context to support exceptions and dynamic-wind. The starred and circled variants, E^{\star} , E° , F^{\star} , and F° dictate where a single value is promoted to multiple values and where multiple values are demoted to a single value. The U context is used to manage the report's underspecification of the results of set!, setcar!, and set-cdr! (see section A.12 for details). Finally, the S context is where quoted expressions can be simplified. The precise use of the evaluation contexts is explained along with the relevant rules.

To convert the answers (A) of the semantics into observable results, we use these two functions:

They eliminate the store, and replace complex values with simple tags that indicate only the kind of value that was produced or, if no values were produced, indicates that either an uncaught exception was raised, or that the program reached a state that is not specified by the semantics.

A.3. Quote

The first reduction rules that apply to any program is the rules in figure A.3 that eliminate quoted expressions. The first two rules erase the quote for quoted expressions that do not introduce any pairs. The last two rules lift quoted datums to the top of the expression so they are evaluated only once, and turn the datums into calls to either cons or consi, via the metafunctions \mathcal{Q}_i and \mathcal{Q}_m .

Note that the left-hand side of the [6qcons] and [6qconsi] rules are identical, meaning that if one rule applies to a term, so does the other rule. Accordingly, a quoted expression may be lifted out into a sequence of cons expressions, which create mutable pairs, or into a sequence of consi expressions, which create immutable pairs (see section A.7 for the rules on how that happens).

These rules apply before any other because of the contexts in which they, and all of the other rules, apply. In particular, these rule applies in the S context. Figure A.2b shows that the S context allows this reduction to apply in any subexpression of an e, as long as all of the subexpressions to the left have no quoted expressions in them, although expressions to the right may have quoted expressions. Accordingly, this rule applies once for each

quoted expression in the program, moving out to the beginning of the program. The rest of the rules apply in contexts that do not contain any quoted expressions, ensuring that these rules convert all quoted data into lists before those rules apply.

Although the identifier qp does not have a subscript, the semantics of PLT Redex's "fresh" declaration takes special care to ensures that the qp on the right-hand side of the rule is indeed the same as the one in the side-condition.

A.4. Multiple values

The basic strategy for multiple values is to add a rule that demotes (values v) to v and another rule that promotes vto (values v). If we allowed these rules to apply in an arbitrary evaluation context, however, we would get infinite reduction sequences of endless alternation between promotion and demotion. So, the semantics allows demotion only in a context expecting a single value and allows promotion only in a context expecting multiple values. We obtain this behavior with a small extension to the Felleisen-Hieb framework (also present in the operational model for R⁵RS [?]). We extend the notation so that holes have names (written with a subscript), and the context-matching syntax may also demand a hole of a particular name (also written with a subscript, for instance $E[e]_{\star}$). The extension allows us to give different names to the holes in which multiple values are expected and those in which single values are expected, and structure the grammar of contexts accordingly.

To exploit this extension, we use three kinds of holes in the evaluation context grammar in figure A.2b. The ordinary hole [] appears where the usual kinds of evaluation can occur. The hole []_{*} appears in contexts that allow multiple values and []_o appears in contexts that expect a single value. Accordingly, the rule [6promote] only applies in []_{*} contexts, and [6demote] only applies in [] contexts.

To see how the evaluation contexts are organized to ensure that promotion and demotion occur in the right places, consider the F, F^* and F° evaluation contexts. The F^* and F° evaluation contexts are just the same as F, except that they allow promotion to multiple values and demotion to a single value, respectively. So, the F evaluation context, rather than being defined in terms of itself, exploits F^* and F° to dictate where promotion and demotion can occur. For example, F can be (if F° e e) meaning that demotion from (values v) to v can occur in the test of an if expression. Similarly, F can be (begin F^* e e \cdots) meaning that v can be promoted to (values v) in the first subexpression of a begin.

In general, the promotion and demotion rules simplify the definitions of the other rules. For instance, the rule for if does not need to consider multiple values in its first subexpression. Similarly, the rule for begin does not need to consider the case of a single value as its first subexpression.

The other two rules in figure A.4 handle call-with-values. The evaluation contexts for call-with-values (in the F non-terminal) allow evaluation in the body of a procedure that has been passed as the first argument to call-with-values, as long as the second argument has been reduced to a value. Once evaluation inside that procedure completes, it will produce multiple values (since it is an F^{\star} position), and the entire call-with-values expression reduces to an application of its second argument to those values, via the rule [6cwvd]. Finally, in the case that the first argument to call-with-values is a value, but is not of the form (lambda () e), the rule [6cwvw] wraps it in a thunk to trigger evaluation.

A.5. Exceptions

The workhorses for the exception system are

 $(\text{handlers } proc \cdots e)$

expressions and the G and PG evaluation contexts (shown in figure A.2b). The handlers expression records the active exception handlers ($proc \cdots$) in some expression (e). The intention is that only the nearest enclosing handlers expression is relevant to raised exceptions, and the G and PG evaluation contexts help achieve that goal. They are just like their counterparts E and P, except that handlers expressions cannot occur on the path to the hole, and the exception system rules take advantage of that context to find the closest enclosing handler.

To see how the contexts work together with handler expressions, consider the left-hand side of the [6xunee] rule in figure A.5. It matches expressions that have a call to raise or raise-continuable (the non-terminal raise* matches both exception-raising procedures) in a PG evaluation context. Since the PG context does not contain any handlers expressions, this exception cannot be caught, so this expression reduces to a final state indicating the uncaught exception. The rule [6xuneh] also signals an uncaught exception, but it covers the case where a handlers expression has exhausted all of the handlers available to it. The rule applies to expressions that have a handlers expression (with no exception handlers) in an arbitrary evaluation context where a call to one of the exceptionraising functions is nested in the handlers expression. The use of the G evaluation context ensures that there are no other handler expressions between this one and the raise.

The next two rules cover call to the procedure with-exception-handler. The [6xwh1] rule applies when there are no handler expressions. It constructs a new one and applies v_2 as a thunk in the handler body. If there already is a handler expression, the [6xwhn] applies. It collects the current handlers and adds the new one into a new handlers expression and, as with the previous rule, invokes the second argument to with-exception-handlers.

The next two rules cover exceptions that are raised in the context of a handlers expression. If a continuable exception is raised, [6xrc] applies. It takes the most recently installed handler from the nearest enclosing handlers expression and applies it to the argument to raise-continuable, but in a context where the exception handlers do not include that latest handler. The [6xr] rule behaves similarly, except it raises a new exception if the handler returns. The new exception is created with the make-cond special form.

The make-cond special form is a stand-in for the report's conditions. It does not evaluate its argument (note its absence from the E grammar in figure A.2b). That argument is just a literal string describing the context in which the exception was raised. The only operation on conditions is condition?, whose semantics are given by the two rules [6ct] and [6cf].

Finally, the rule [6xdone] drops a handlers expression when its body is fully evaluated, and the rule [6weherr] raises an exception when with-exception-handler is supplied with incorrect arguments.

A.6. Arithmetic and basic forms

This model does not include the report's arithmetic, but does include an idealized form in order to make experimentation with other features and writing test suites for the model simpler. Figure A.6 shows the reduction rules for the primitive procedures that implement addition, subtraction, multiplication, and division. They defer to their mathematical analogues. In addition, when the subtraction or divison operator are applied to no arguments, or when division receives a zero as a divisor, or when any of the arithmetic operations receive a non-number, an exception is raised.

The bottom half of figure A.6 shows the rules for if, begin, and begin0. The relevant evaluation contexts are given by the F non-terminal.

The evaluation contexts for if only allow evaluation in its test expression. Once that is a value, the rules reduce an if expression to its consequent if the test is not #f, and to its alternative if it is #f.

The begin evaluation contexts allow evaluation in the first subexpression of a begin, but only if there are two or more Рис. A.7: Lists

Рис. А.8: Eqv

subexpressions. In that case, once the first expression has been fully simplified, the reduction rules drop its value. If there is only a single subexpression, the begin itself is dropped.

Like the begin evaluation contexts, the begin 0 evaluation contexts allow evaluation of the first subexpression of a begin0 expression when there are two or more subexpressions. The begin0 evaluation contexts also allow evaluation in the second subexpression of a begin0 expression, as long as the first subexpression has been fully simplified. The [6begin0n] rule for begin0 then drops a fully simplified second subexpression. Eventually, there is only a single expression in the begin0, at which point the [begin01] rule fires, and removes the begin0 expression.

A.7. Lists

The rules in figure A.7 handle lists. The first two rules handle list by reducing it to a succession of calls to cons, followed by null.

The next two rules, [6cons] and [6consi], allocate new cons cells. They both move (cons v_1 v_2) into the store, bound to a fresh pair pointer (see also section A.3 for a description of "fresh"). The [6cons] uses a mp variable, to indicate the pair is mutable, and the [6consi] uses a ip variable to indicate the pair is immutable.

The rules [6car] and [6cdr] extract the components of a pair from the store when presented with a pair pointer (the pp can be either mp or ip, as shown in figure A.2a).

The rules [6setcar] and [6setcdr] handle assignment of mutable pairs. They replace the contents of the appropriate location in the store with the new value, and reduce to unspecified. See section A.12 for an explanation of how unspecified reduces.

The next four rules handle the null? predicate and the pair? predicate, and the final four rules raise exceptions when car, cdr, set-car! or set-cdr! receive non pairs.

A.8. Eqv

The rules for equ? are shown in figure A.8. The first two rules cover most of the behavior of eqv?. The first says that when the two arguments to eqv? are syntactically identical, then eqv? produces #t and the second says that when the arguments are not syntactically identical, then eqv? produces #f. The structure of v has been carefully designed so that simple term equality corresponds closely to eqv?'s behavior. For example, pairs are represented as pointers into the store and eqv? only compares those pointers.

The side-conditions on those first two rules ensure that they do not apply when simple term equality does not match the behavior of eqv?. There are two situations where it does not match: comparing two conditions and comparing two procedures. For the first, the report does not specify eqv?'s behavior, except to say that it must return a boolean, so the remaining two rules ([6eqct], and [6eqcf]) allow such comparisons to return #t or #f. Comparing two procedures is covered in section A.12.

A.9. Procedures and application

In evaluating a procedure call, the report leaves unspecified the order in which arguments are evaluated. So, our reduction system allows multiple, different reductions to occur, one for each possible order of evaluation.

To capture unspecified evaluation order but allow only evaluation that is consistent with some sequential ordering of the evaluation of an application's subexpressions, we use nondeterministic choice to first pick a subexpression to reduce only when we have not already committed to reducing some other subexpression. To achieve that effect, we limit the evaluation of application expressions to only those that have a single expression that is not fully reduced, as shown in the non-terminal F, in figure A.2b. To evaluate application expressions that have more than two arguments to evaluate, the rule [6mark] picks one of the subexpressions of an application that is not fully simplified and lifts it out in its own application, allowing it to be evaluated. Once one of the lifted expressions is evaluated, the [6appN] substitutes its value back into the original application.

The [6appN] rule also handles other applications whose arguments are finished by substituting the first argument for the first formal parameter in the expression. Its side-condition uses the relation in figure A.9b to ensure that there are no set! expressions with the parameter x_1 as a target. If there is such an assignment, the [6appN!] rule applies (see also section A.3 for a

Рис. A.9b: Variable-assignment relation

description of "fresh"). Instead of directly substituting the actual parameter for the formal parameter, it creates a new location in the store, initially bound the actual parameter, and substitutes a variable standing for that location in place of the formal parameter. The store, then, handles any eventual assignment to the parameter. Once all of the parameters have been substituted away, the rule [6app0] applies and evaluation of the body of the procedure begins.

At first glance, the rule [6appN] appears superfluous, since it seems like the rules could just reduce first by [6appN!] and then look up the variable when it is evaluated. There are two reasons why we keep the [6appN], however. The first is purely conventional: reducing applications via substitution is taught to us at an early age and is commonly used in rewriting systems in the literature. The second reason is more technical: the [6mark] rule requires that [6appN] be applied once e_i has been reduced to a value. [6appN!] would lift the value into the store and put a variable reference into the application, leading to another use of [6mark], and another use of [6appN!], which continues forever.

The rule $[6\mu app]$ handles a well-formed application of a function with a dotted parameter lists. It such an application into an application of an ordinary procedure by constructing a list of the extra arguments. Similarly, the rule $[6\mu app1]$ handles an application of a procedure that has a single variable as its parameter list.

The rule [6var] handles variable lookup in the store and [6set] handles variable assignment.

The next two rules [6proct] and [6procf] handle applications of procedure?, and the remaining rules cover applications of non-procedures and arity violations.

The rules in figure A.9c cover apply. The first rule, [6applyf], covers the case where the last argument to apply is the empty list, and simply reduces by erasing the empty list and the apply. The second rule, [6applyc] covers a well-formed application of apply where apply's final argument is a pair. It reduces by extracting the components of the pair from the store and putting them into the application of apply. Repeated application of this rule thus extracts all of the list elements passed to apply out of the store

The remaining five rules cover the various violations that can occur when using apply. The first one covers the case where apply is supplied with a cyclic list. The next four cover applying a non-procedure, passing a non-list as the last argument, and supplying too few arguments to apply.

A.10. Call/cc and dynamic wind

The specification of dynamic-wind uses $(dw \ x \ e \ e \ e)$ expressions to record which dynamic-wind thunks are active at each point in the computation. Its first argument is an identifier that is globally unique and serves to identify invocations of dynamic-wind, in order to avoid exiting and re-entering the same dynamic context during a continuation switch. The second, third, and fourth arguments are calls to some before, thunk, and after procedures from a call to dynamic-wind. Evaluation only occurs in the middle expression; the dw expression only serves to record which before and after procedures need to be run during a continuation switch. Accordingly, the reduction rule for an application of dynamic-wind reduces to a call to the before procedure, a dw expression and a call to the after procedure, as shown in rule [6wind] in figure A.10. The next two rules cover abuses of the dynamic-wind procedure: calling it with nonprocedures, and calling it with the wrong number of arguments. The [6dwdone] rule erases a dw expression when its second argument has finished evaluating.

The next two rules cover call/cc. The rule [6call/cc] creates a new continuation. It takes the context of the call/cc expression and packages it up into a throw expression that represents the continuation. The throw expression uses the fresh variable x to record where the application of call/cc occurred in the context for use in the [6throw] rule when the continuation is applied. That rule takes the arguments of the continuation, wraps them with a call to values, and puts them back into the place where the original call to call/cc occurred, replacing the current context with the context returned by the $\mathscr T$ metafunction.

The \mathscr{T} (for "trim") metafunction accepts two D contexts and builds a context that matches its second argument, the destination context, except that additional calls to the *before* and *after* procedures from dw expressions in the context have been added.

The first clause of the \mathscr{T} metafunction exploits the H context, a context that contains everything except dw expressions. It ensures that shared parts of the dynamic-wind context are ignored, recurring deeper into the two expression contexts as long as the first dw expression in each have matching identifiers (x_1) . The final rule is a catchall; it only applies when all the others fail and thus applies either when there are no dws in the context, or when the dw expressions do not match. It calls the two other metafunctions defined in figure A.10 and puts their results together into a begin expression.

The \mathscr{R} metafunction extracts all of the *before* procedures from its argument and the \mathscr{S} metafunction extracts all of the *after*

Рис. A.10: Call/cc and dynamic wind

procedures from its argument. They each construct new contexts and exploit H to work through their arguments, one dw at a time. In each case, the metafunctions are careful to keep the right dw context around each of the procedures in case a continuation jump occurs during one of their evaluations. Since \mathcal{R} , receives the destination context, it keeps the intermediate parts of the context in its result. In contrast $\mathscr S$ discards all of the context except the dws, since that was the context where the call to the continuation occurred

A.11. Letrec

Figre A.11 shows the rules that handle letrec and letrec* and the supplementary expressions that they produce, 1! and reinit. As a first approximation, both letrec and letrec* reduce by allocating locations in the store to hold the values of the init expressions, initializing those locations to bh (for "black hole"), evaluating the init expressions, and then using 1! to update the locations in the store with the value of the init expressions. They also use reinit to detect when an init expression in a letrec is reentered via a continuation.

Before considering how letrec and letrec* use 1! and reinit, first consider how 1! and reinit behave. The first two rules in figure A.11 cover 1!. It behaves very much like set!, but it initializes both ordinary variables, and variables that are current bound to the black hole (bh).

The next two rules cover ordinary set! when applied to a variable that is currently bound to a black hole. This situation can arise when the program assigns to a variable before letrec initializes it, eg (letrec ((x (set! x 5))) x). The report specifies that either an implementation should perform the assignment, as reflected in the [6setdt] rule or it raise an exception, as reflected in the [6setdte] rule.

The [6dt] rule covers the case where a variable is referred to before the value of a init expression is filled in, which must always raise an exception.

A reinit expression is used to detect a program that captures a continuation in an initialization expression and returns to it, as shown in the three rules [6init], [6reinit], and [6reinite]. The reinit form accepts an identifier that is bound in the store to a boolean as its argument. Those are identifiers are initially #f. When reinit is evaluated, it checks the value of the variable and, if it is still #f, it changes it to #t. If it is already #t, then reinit either just does nothing, or it raises an exception, in keeping with the two legal behaviors of letrec and letrec*.

The last two rules in figure A.11 put together 1! and reinit. The [6letrec] rule reduces a letrec expression to an application expression, in order to capture the unspecified order of evaluation of the init expressions. Each init expression is wrapped in a begin0 that records the value of the init and then uses reinit to detect continuations that return to the init expression. Once all of the init expressions have been evaluated, the procedure on the right-hand side of the rule is invoked, causing the value of the init expression to be filled in the store, and evaluation continues with the body of the original letrec expression.

The [6letrec*] rule behaves similarly, but uses a begin expression rather than an application, since the init expressions are evaluated from left to right. Moreover, each init expression is filled into the store as it is evaluated, so that subsequent init expressions can refer to its value.

A.12. Underspecification

The rules in figure A.12 cover aspects of the semantics that are explicitly unspecified. Implementations can replace the rules [6ueqv], [6uval] and with different rules that cover the left-hand sides and, as long as they follow the informal specification, any replacement is valid. Those three situations correspond to the case when eqv? applied to two procedures and when multiple values are used in a single-value context.

The remaining rules in figure A.12 cover the results from the assignment operations, set!, set-car!, and set-cdr!. An implementation does not adjust those rules, but instead renders them useless by adjusting the rules that insert unspecified: [6setcar], [6setcdr], [6set], and [6setd]. Those rules can be adjusted by replacing unspecified with any number of values in those rules.

So, the remaining rules just specify the minimal behavior that we know that a value or values must have and otherwise reduce to an unknown: state. The rule [6udemand] drops unspecified in the U context. See figure A.2b for the precise definition of U, but intuitively it is a context that is only a single expression layer deep that contains expressions whose value depends on the value of their subexpressions, like the first subexpression of a if. Following that are rules that discard unspecified in expressions that discard the results of some of their subexpressions. The [6ubegin] shows how begin discards its first expression when there are more expressions to evaluate. The next two rules, [6uhandlers] and [6udw] propagate unspecified to their context, since they also return any number of values to their context. Finally,

Рис. A.12: Explicitly unspecified behavior

the two begin0 rules preserve unspecified until the rule [6begin01] can return it to its context.

Приложение B. Sample definitions for derived forms

This appendix contains sample definitions for some of the keywords described in this report in terms of simpler forms:

cond

The cond keyword (section 11.4.5) could be defined in terms of if, let and begin using syntax-rules as follows:

```
(define-syntax cond
 (syntax-rules (else =>)
   ((cond (else result1 result2 ...))
    (begin result1 result2 ...))
   ((cond (test => result))
    (let ((temp test))
      (if temp (result temp))))
   ((cond (test => result) clause1 clause2 ...)
    (let ((temp test))
      (if temp
         (result temp)
         (cond clause1 clause2 ...))))
   ((cond (test)) test)
   ((cond (test) clause1 clause2 ...)
    (let ((temp test))
      (if temp
         temp
         (cond clause1 clause2 ...))))
   ((cond (test result1 result2 ...))
    (if test (begin result1 result2 ...)))
   ((cond (test result1 result2 ...)
         clause1 clause2 ...)
    (if test
        (begin result1 result2 ...)
        (cond clause1 clause2 ...)))))
```

case

The case keyword (section 11.4.5) could be defined in terms of let, cond, and memv (see library chapter ??) using syntax-rules as follows:

```
(else else-res1 else-res2 ...))
(let ((tmp expr0))
  (cond
          ((memv tmp '(key ...)) res1 res2 ...)
          ...
          (else else-res1 else-res2 ...))))
((case expr0
          ((keya ...) res1a res2a ...)
          ((keyb ...) res1b res2b ...)
          ...)
(let ((tmp expr0))
          (cond
               ((memv tmp '(keya ...)) res1a res2a ...)
                ((memv tmp '(keyb ...)) res1b res2b ...)
                ...)
)))))
```

let*

The let* keyword (section 11.4.6) could be defined in terms of let using syntax-rules as follows:

```
(define-syntax let*
  (syntax-rules ()
     ((let* () body1 body2 ...)
     (let () body1 body2 ...))
     ((let* ((name1 expr1) (name2 expr2) ...)
        body1 body2 ...)
     (let ((name1 expr1))
        (let* ((name2 expr2) ...)
        body1 body2 ...)))))
```

letrec

The letrec keyword (section 11.4.6) could be defined approximately in terms of let and set! using syntaxrules, using a helper to generate the temporary variables needed to hold the values before the assignments are made, as follows:

```
(define-syntax letrec
  (syntax-rules ()
     ((letrec () body1 body2 ...)
      (let () body1 body2 ...))
     ((letrec ((var init) ...) body1 body2 ...)
      (letrec-helper
          (var ...)
          ()
          ((var init) ...)
          body1 body2 ...))))

(define-syntax letrec-helper
     (syntax-rules ()
```

```
((letrec-helper
  ()
  (temp ...)
  ((var init) ...)
  body1 body2 ...)
(let ((var <undefined>) ...)
  (let ((temp init) ...)
    (set! var temp)
    . . . )
  (let () body1 body2 ...)))
((letrec-helper
  (x y ...)
  (temp ...)
  ((var init) ...)
  body1 body2 ...)
(letrec-helper
  (y ...)
  (newtemp temp ...)
  ((var init) ...)
  body1 body2 ...))))
```

The syntax <undefined> represents an expression that returns something that, when stored in a location, causes an exception with condition type &assertion to be raised if an attempt to read from or write to the location occurs before the assignments generated by the letrec transformation take place. (No such expression is defined in Scheme.)

A simpler definition using syntax-case and generatetemporaries is given in library chapter ??.

letrec*

The letrec* keyword could be defined approximately in terms of let and set! using syntax-rules as follows:

```
(define-syntax letrec*
 (syntax-rules ()
   ((letrec* ((var1 init1) ...) body1 body2 ...)
    (let ((var1 <undefined>) ...)
      (set! var1 init1)
      (let () body1 body2 ...)))))
```

The syntax <undefined> is as in the definition of letrec above.

let-values

The following definition of let-values (section 11.4.6) using syntax-rules employs a pair of helpers to create temporary names for the formals.

```
(define-syntax let-values
 (syntax-rules ()
   ((let-values (binding ...) body1 body2 ...)
    (let-values-helper1
      (binding ...)
     body1 body2 ...))))
(define-syntax let-values-helper1
```

```
;; map over the bindings
 (syntax-rules ()
   ((let-values
      ((id temp) ...)
     body1 body2 ...)
    (let ((id temp) ...) body1 body2 ...))
   ((let-values
     assocs
     ((formals1 expr1) (formals2 expr2) ...)
     body1 body2 ...)
    (let-values-helper2
     formals1
     ()
     expr1
     assocs
     ((formals2 expr2) ...)
     body1 body2 ...))))
(define-syntax let-values-helper2
 ;; create temporaries for the formals
 (syntax-rules ()
   ((let-values-helper2
     temp-formals
     expr1
     assocs
     bindings
     body1 body2 ...)
    (call-with-values
      (lambda () expr1)
      (lambda temp-formals
       (let-values-helper1
         assocs
         bindings
         body1 body2 ...)))
   ((let-values-helper2
      (first . rest)
      (temp ...)
     expr1
      (assoc ...)
     bindings
     body1 body2 ...)
    (let-values-helper2
     rest
      (temp ... newtemp)
     expr1
      (assoc ... (first newtemp))
     bindings
     body1 body2 ...))
   ((let-values-helper2
     rest-formal
     (temp ...)
     expr1
     (assoc ...)
     bindings
     body1 body2 ...)
    (call-with-values
      (lambda () expr1)
      (lambda (temp ... . newtemp)
       (let-values-helper1
         (assoc ... (rest-formal newtemp))
         bindings
```

```
body1 body2 ...)))))
```

let*-values

The following macro defines let*-values in terms of let and let-values using syntax-rules:

```
(define-syntax let*-values
 (syntax-rules ()
   ((let*-values () body1 body2 ...)
    (let () body1 body2 ...))
   ((let*-values (binding1 binding2 ...)
     body1 body2 ...)
    (let-values (binding1)
      (let*-values (binding2 ...)
       body1 body2 ...))))
```

let

The let keyword could be defined in terms of lambda and letrec using syntax-rules as follows:

```
(define-syntax let
 (syntax-rules ()
   ((let ((name val) ...) body1 body2 ...)
    ((lambda (name ...) body1 body2 ...)
     val ...))
   ((let tag ((name val) ...) body1 body2 ...)
    ((letrec ((tag (lambda (name ...)
                  body1 body2 ...)))
      tag)
     val ...))))
```

Приложение С. Additional material

This report itself, as well as more material related to this report such as reference implementations of some parts of Scheme and archives of mailing lists discussing this report is at

```
http://www.r6rs.org/
```

The Schemers web site at

```
http://www.schemers.org/
```

as well as the Readscheme site at

```
http://library.readscheme.org/
```

contain extensive Scheme bibliographies, as well as papers, programs, implementations, and other material related to Scheme.

Приложение D. **Example**

This section describes an example consisting of the (rungekutta) library, which provides an integrate-system procedure that integrates the system

$$y'_k = f_k(y_1, y_2, \dots, y_n), \ k = 1, \dots, n$$

of differential equations with the method of Runge-Kutta.

As the (runge-kutta) library makes use of the (rnrs base (6)) library, its skeleton is as follows:

```
#!r6rs
(library (runge-kutta)
  (export integrate-system
        head tail)
  (import (rnrs base))
 ⟨library body⟩)
```

The procedure definitions described below go in the place of (library body).

The parameter system-derivative is a function that takes a system state (a vector of values for the state variables y_1, \ldots, y_n) and produces a system derivative (the values y'_1, \ldots, y'_n). The parameter initial-state provides an initial system state, and h is an initial guess for the length of the integration step.

The value returned by integrate-system is an infinite stream of system states.

```
(define integrate-system
 (lambda (system-derivative initial-state h)
   (let ((next (runge-kutta-4 system-derivative h)))
     (letrec ((states
             (cons initial-state
                  (lambda ()
                    (map-streams next states)))))
      states))))
```

The runge-kutta-4 procedure takes a function, f, that produces a system derivative from a system state. The rungekutta-4 procedure produces a function that takes a system state and produces a new system state.

```
(define runge-kutta-4
 (lambda (f h)
   (let ((*h (scale-vector h))
        (*2 (scale-vector 2))
        (*1/2 (scale-vector (/ 1 2)))
        (*1/6 (scale-vector (/ 1 6))))
     (lambda (y)
      ;; y is a system state
      (let* ((k0 (*h (f y)))
             (k1 (*h (f (add-vectors y (*1/2 k0)))))
             (k2 (*h (f (add-vectors y (*1/2 k1)))))
             (k3 (*h (f (add-vectors y k2)))))
        (add-vectors y
          (*1/6 (add-vectors k0
                           (*2 k1)
                           (*2 k2)
                           k3))))))))
(define elementwise
 (lambda (f)
   (lambda vectors
     (generate-vector
       (vector-length (car vectors))
       (lambda (i)
        (apply f
               (map (lambda (v) (vector-ref v i))
                   vectors)))))))
(define generate-vector
 (lambda (size proc)
```

```
(let ((ans (make-vector size)))
     (letrec ((loop
              (lambda (i)
                (cond ((= i size) ans)
                     (else
                      (vector-set! ans i (proc i))
                      (loop (+ i 1))))))
       (loop 0)))))
(define add-vectors (elementwise +))
(define scale-vector
 (lambda (s)
   (elementwise (lambda (x) (* x s)))))
```

The map-streams procedure is analogous to map: it applies its first argument (a procedure) to all the elements of its second argument (a stream).

```
(define map-streams
 (lambda (f s)
   (cons (f (head s))
        (lambda () (map-streams f (tail s))))))
```

Infinite streams are implemented as pairs whose car holds the first element of the stream and whose cdr holds a procedure that delivers the rest of the stream.

```
(define head car)
(define tail
 (lambda (stream) ((cdr stream))))
```

The following program illustrates the use of integratesystem in integrating the system

$$C\frac{dv_C}{dt} = -i_L - \frac{v_C}{R}$$

$$L\frac{di_L}{dt} = v_C$$

which models a damped oscillator.

```
#!r6rs
(import (rnrs base)
       (rnrs io simple)
       (runge-kutta))
(define damped-oscillator
 (lambda (R L C)
   (lambda (state)
     (let ((Vc (vector-ref state 0))
          (Il (vector-ref state 1)))
       (vector (- 0 (+ (/ Vc (* R C)) (/ Il C)))
              (/ Vc L))))))
(define the-states
 (integrate-system
    (damped-oscillator 10000 1000 .001)
    '#(1 0)
    .01))
(letrec ((loop (lambda (s)
               (newline)
```

```
(write (head s))
             (loop (tail s)))))
(loop the-states))
```

This prints output like the following:

```
#(10)
#(0.99895054 9.994835e-6)
#(0.99780226 1.9978681e-5)
#(0.9965554 2.9950552e-5)
#(0.9952102 3.990946e-5)
#(0.99376684 4.985443e-5)
#(0.99222565 5.9784474e-5)
#(0.9905868 6.969862e-5)
#(0.9888506 7.9595884e-5)
#(0.9870173 8.94753e-5)
```

Приложение Е. Language changes

This chapter describes most of the changes that have been made to Scheme since the "Revised⁵ Report" [?] was published:

- Scheme source code now uses the Unicode character set. Specifically, the character set that can be used for identifiers has been greatly expanded.
- Identifiers can now start with the characters ->.
- Identifiers and symbol literals are now case-sensitive.
- Identifiers and representations of characters, booleans, number objects, and . must be explicitly delimited.
- # is now a delimiter.
- Bytevector literal syntax has been added.
- Matched square brackets can be used synonymously with parentheses.
- The read-syntax abbreviations #' (for syntax), #□ (for quasisyntax), #, (for unsyntax), and #,@ (for unsyntax-splicing have been added; see section 4.3.5.)
- # can no longer be used in place of digits in number representations.
- The external representation of number objects can now include a mantissa width.
- Literals for NaNs and infinities were added
- String and character literals can now use a variety of escape sequences.
- Block and datum comments have been added.
- The #!r6rs comment for marking report-compliant lexical syntax has been added.
- Characters are now specified to correspond to Unicode scalar values.

72 Revised⁶ Scheme

- Many of the procedures and syntactic forms of the language are now part of the (rnrs base (6)) library. Some procedures and syntactic forms have been moved to other libraries; see figure A.1.
- The base language has the following new procedures and syntactic forms: letrec*, let-values, let*-values, real-valued?, rational-valued?, integer-valued?, exact, inexact, finite?, infinite?, nan?, div, mod, div-and-mod, div0, mod0, div0-and-mod0, exact-integer-sqrt, boolean=?, symbol=?, string-foreach, vector-map, vector-for-each, error, assertion-violation, assert, call/cc, identifier-syntax.
- The following procedures have been removed: charready?, transcript-on, transcript-off, load.
- The case-insensitive string comparisons (string-ci=?, string-ci<?, string-ci>?, string-ci<?, string-ci>?) operate on the case-folded versions of the strings rather than as the simple lexicographic ordering induced by the corresponding character comparison procedures.
- Libraries have been added to the language.
- A number of standard libraries are described in a separate report [?].
- Many situations that "were an error" now have defined or constrained behavior. In particular, many are now specified in terms of the exception system.
- The full numerical tower is now required.
- The semantics for the transcendental functions has been specified more fully.
- The semantics of expt for zero bases has been refined.
- In syntax-rules forms, a _ may be used in place of the keyword.
- The let-syntax and letrec-syntax no longer introduce a new environment for their bodies.
- For implementations that support NaNs or infinities, many arithmetic operations have been specified on these values consistently with IEEE 754.
- For implementations that support a distinct -0.0, the semantics of many arithmetic operations with regard to -0.0 has been specified consistently with IEEE 754.
- Scheme's real number objects now have an exact zero as their imaginary part.
- The specification of quasiquote has been extended. Nested quasiquotations work correctly now, and unquote and unquote-splicing have been extended to several operands.

- Procedures now may or may not refer to locations.
 Consequently, eqv? is now unspecified in a few cases where it was specified before.
- The mutability of the values of quasiquote structures has been specified to some degree.
- The dynamic environment of the *before* and *after* procedures of dynamic-wind is now specified.
- Various expressions that have only side effects are now allowed to return an arbitrary number of values.
- The order and semantics for macro expansion has been more fully specified.
- Internal definitions are now defined in terms of letrec*.
- The old notion of program structure and Scheme's top-level environment has been replaced by top-level programs and libraries.
- The denotational semantics has been replaced by an operational semantics based on an earlier semantics for the language of the "Revised⁵ Report" [?, ?].
